## *Preface*

The book **OPERATIONS RESEARCH – Expositions in Mathcad** is concise matter made during several years of teaching at the Technical Faculty “Mihailo Pupin” in Zrenjanin. Subject matter of this book can be equally interesting to students of many profiles of this faculty: informatics teachers, informatics engineers, technicians and informatics teachers and to graduated engineers for management of technical systems and to the others. The book contains algorithms in operations research field that are mostly mathematically oriented. Its chapters treat:

- $\pi$  *Linear programming*
- $\pi$  *Transportation problem*
- $\pi$  *Assignment problem of workplaces*
- $\pi$  *Nonlinear programming*
- $\pi$  *Dynamic programming*
- $\pi$  *Multicriteria optimization*
- $\pi$  *Heuristic research*
- $\pi$  *Markov chains*
- $\pi$  *Mass queueing*
- $\pi$  *Simulation modelling (Monte-Carlo)*
- $\pi$  *Game theory*
- $\pi$  *Inventory control*
- $\pi$  *Network planning*
- $\pi$  *Testing statistical hypotheses.*

After introductory informing about the history of the subject matter field, follow the problems exposed in the chapters of the cited sequence. Each chapter contains mathematical proceedings without detailed proofs, with accent on pragmatism and applicability of methods and proceedings of operations research. An accompanying CD completes the contents of the book and offers students sufficient and necessary matter through representative files, sorted according to chapters (folders).

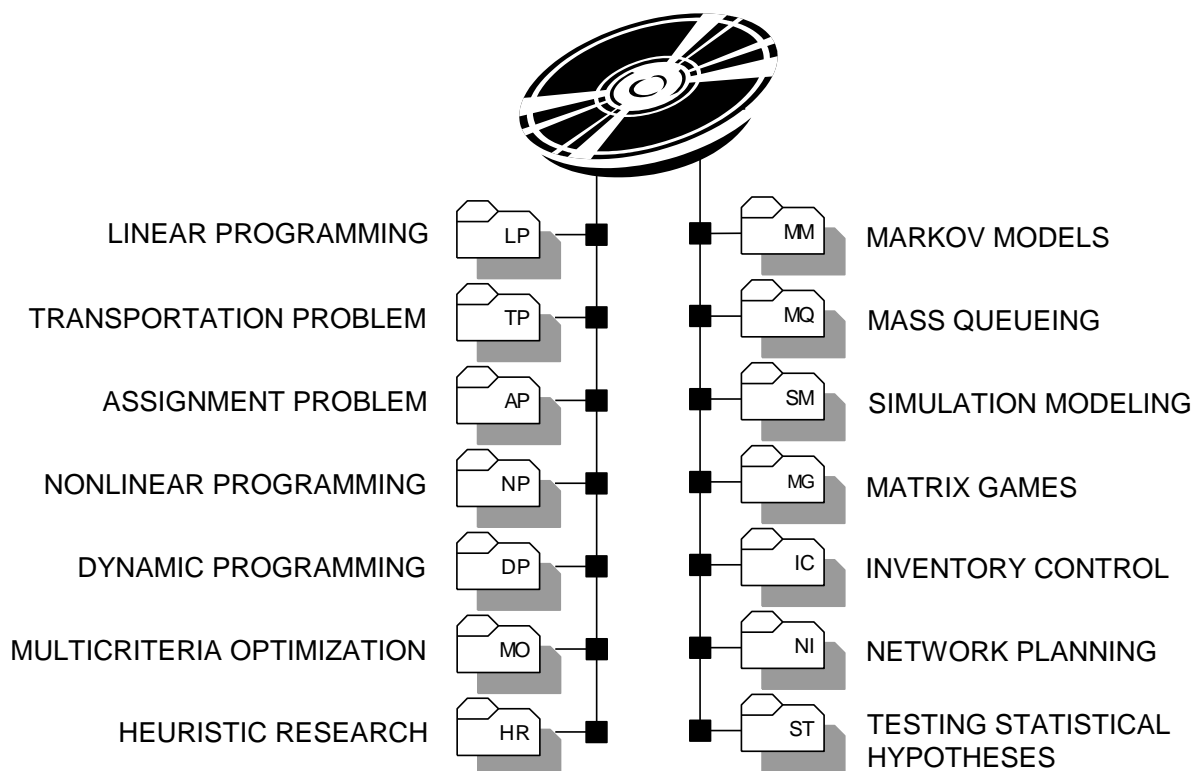

The authors express their acknowledgement to PhD Milan Bojanović, director of the company CPS-CAD Professional Sys. from Belgrade and Mr Srđan Šerer, senior lecturer of English language, for useful suggestions at final editing of this textbook. We especially express our thanks to the reviewers of this textbook, PhD Mirko Vujošević from the Faculty of Organizational Sciences from Belgrade, PhD Dragan Radojević from the Institute “Mihailo Pupin” in Belgrade and doc. Detelin Vasilev, PhD, from Higher school of transport “Todor Kableškov” in Sofia.

## u Basic Structure of OR Tutorial

**Note** All textual and/or picture information published in this book and taken over from the site PTC, are taken on by consent of CPS-CAD Professional Sys. Company, Belgrade, that is official distributor of the software package Mathcad for the Republic of Serbia. To the editor printing of the book is approved.

## OPERATIONS RESEARCH DEVELOPMENT

In computer mathematics, for models of often very complex structures, very quickly are being developed numerical methods of optimization. Their problems are studying extreme values of criteria functions with argument optimal values. We need to stress especially tasks of mathematical programming. Knowing their essentials, we can solve many tasks in production and business. Operations research and management science include also optimization tasks, as well appropriate methods elaborated for their solving. Stability of computing methods and algorithms comprises one of main trends in researching the application and classification of various mistakes with implementing these methods. In the beginning of the 20th century, in 1916, begins development of management science, founded by Frederick Taylor [2]. With this have been solved several substantial matters, and they, predominantly, refer to resources management. In those years Harris has set fundamental mathematical model of optimal inventory level. The emergence of queueing theory referred to Danish mathematician A.K. Erlang (1909). Their contributions to the theory of optimal inventory have given, among others: Kendal, Lee, Hinchin and Polachek. Game theory is mathematical theory about decision making in competitor situations of opposite interests. The first to begin its developing, was Emile Borel in 1921, and fundamental contribution was given in 1928 by Von Neumann (1903-1957). Its first examples of modelling linear programming and transport problem were exposed in Kantorovich's papers in 1939, and in Neumann's work in 1936. Sudden development of this theory and praxis followed after the second world war. A transportation problem pioneer is also American mathematician Hitchcock from 1941. He was one of the first to formulate and solve one type of transportation assignments. There are also Vogel's papers dedicated to the approximate method for finding the initial transport solution. The papers of Ford, Falkerson, Charnes, Cuper and others. All these were preconditions to form a team of scientists on the eve of the second world war in Great Britain. They were from different fields but they were included into researches of multiple operations connected to coordination and arrangement of radar systems, military resources transport and the like. These operations researchers have used mathematical methods, and so they have created multidisciplinary science named Operations research. After the war its methods were very quickly implemented solving problems in production and business, medicine, industry and the like. Great importance had simplex, a linear programming method developed in 1947 by a famous American mathematician Danzig [9]. In the period 1951-1955 this method was modified by Charnes, Lemke and Danzig himself [9]. During fifties were being strongly stressed linear programming and statistical methods. During the same decade Neumann and Morgenstern have set a modern game theory. Since Neumann the term "games" has been used as a scientific metaphor for communication among the experts for whom is substantial result of mutual strategies interaction of two or more parties that have conflict interests. The fifties were marked by the beginnings of non-linear programming by Kun and Tucker. This have caused eventful development of new methods and applying of operations research. The known numerical simulation method Monte Carlo was created in 1948, when appeared the paper of Metropolis and Ulman about random numbers. It has been used both for solving deterministic and stochastic tasks in many scientific spheres: reliability theory, meteorology, production, mass queueing, nuclear physics and the like. As logical continuation of traditional Gant's diagram applying towards the end of fifties of last century, there was developed the set of methods that is called network planning technologies. These methods are established on results of algebra, graph theory, statistics and computing sciences. The first study with essential assumptions of this method was published by Walker and Kelly in 1958. The development of PERT method began in 1958. The

research was led by Fazar and mathematical bases of the method were established by Clark in 1958 [15]. Dynamic programming (DP) and algorithms of optimal management were set by American scientist Belman in 1952. He developed classical methodology for modelling and solving of one class of specially structured optimizing tasks connected with so-called multiphasal management processes. During 1960s great influence have had: network planning, linear programming, graph theory in optimization and discrete stochastic simulation. 1970s are characteristic with non-linear programming and global optimization, as well with computer methods based on numerical mathematics. Then have been significantly developed theoretical bases with new algorithms in uncertainty approach, when classical statistical and probability models have not been any more exclusively used. A significant technology was developed in the beginning of 70s. It was named PDM or “precedence diagramming method”. The algorithms of this method are built today in nearly all program packets for network planning. So, this highly elaborated technology is perhaps most of all others from the research field, applicable in praxis. In 80s the attention of operations research is directed to multicriteria optimisation and decision making theory. Expert systems and the systems for decision making support enable introducing personal computers with appropriate program support. More recent methods, established on the theory of “fuzzy sets” in the world of science were published by Zadeh in 1965. Nowadays there are numerous methods based on fuzzy principle: “As closer we watch real problem, its solution becomes more and more fuzzy” (Zadeh), so that the theory of fuzzy sets has appropriately been applied in technical systems management [3], [25]. During 90s have been done significant penetrations in solving the problems of integer, mixed and multicriteria programming. Enormous computer resources become mass available and enable efficient application of operations research method in daily real systems and processes. The development of new approaches for solving such problems, comprises on the basis of heuristics: genetic algorithms, neuron networks and the like. Gradually were being created the tools for solving the problems that will be applied in new technological circumstances, internet environment and electronic business. Besides, we can say that an incomplete evolution in terminology has happened, so that nowadays, attention is paid to operational management, not only to their research.

## 1. LINEAR PROGRAMMING

### 1.1 Optimization of production program [LP1.mcd]

**Example** The factory produces two types of products P1 and P2. The production is being run on two machines. For the first product processing the operation times are: 4 hours/piece on the first machine and 10 hours/piece on the second machine. For processing the second product, these times are: 5 hours/piece on the first machine, and 6 hours/piece on the second machine. Effective capacities of the machines can be used to the atmost 750 and 850 hours respectively. The products appear at the market with minimal quantity of 40 pieces for P1 and 65 pieces for P2. Determine maximal production profit and optimal product quantities by the linear programming method, if the product unit prices are  $c_1 = 5500$  mu/piece (mu=monetary unit) for P1 and  $c_2 = 2800$  mu/piece for P2.

**Solution:**

Criterion function (profit):  $F(x) := 5500 \cdot x_0 + 2800 \cdot x_1$

In that case the vector of the products price is:  $C := (5500 \ 2800)$

Constraints in respect of production and market are:

production:  $4 \cdot x_0 + 5 \cdot x_1 \leq 750$   $10 \cdot x_0 + 6 \cdot x_1 \leq 850$

market:  $x_0 \geq 40$   $x_1 \geq 65$

On account of equalization of relational operators of all four constraints, the last two non-equations can be defined as:

$$A := \begin{pmatrix} 4 & 5 \\ 10 & 6 \\ -1 & 0 \\ 0 & -1 \end{pmatrix} \quad B := \begin{pmatrix} 750 \\ 850 \\ -40 \\ -65 \end{pmatrix}$$

One initial value (it is supposed for the last variable):  $x_1 := 50$

The block for solving the model of linear programming:

$$\text{Given} \quad A \cdot x \leq B \quad x \geq 40$$

The optimal quantities of products P1 and P2 of the production program:

$$Xr := \text{Maximize}(F, x) \quad \text{so the optimal values are:} \quad Xr = \begin{pmatrix} 46 \\ 65 \end{pmatrix}$$

or apart:  $Xr_0 = 46$   $Xr_1 = 65$

The maximum company profit is:  $D := |C \cdot Xr|$   $D = 435000$

$$\text{Arithmetical and logical solution verification are:} \quad A \cdot Xr = \begin{pmatrix} 509 \\ 850 \\ -46 \\ -65 \end{pmatrix} \quad \text{and} \quad A \cdot Xr \geq 0 = \begin{pmatrix} 1 \\ 1 \\ 0 \\ 0 \end{pmatrix}$$

Supplementary variables are:

$$X_d := A \cdot X_r - B$$

$$X_d = \begin{pmatrix} -241 \\ 0 \\ -6 \\ 0 \end{pmatrix}$$

**Note** Alternative procedures for solving this problem are given at the files LP1\_1.mcd.

## 1.2 Optimization of vitamin [LP2.mcd]

**Example** For the production of the vitamin tablets T1, T2 and T3 one factory that produces pharmaceuticals uses the raw materials S1, S2, S3 and S4. The number of vitamin tablets one can get out of one kilogram of raw material is presented in the next table [16].

T.1.1

| $T_i \backslash S_j$ | S1 | S2 | S3 | S4 | Need of tablets (pieces) |
|----------------------|----|----|----|----|--------------------------|
| T1                   | 8  | 6  | 4  | 4  | 18000                    |
| T2                   | 4  | 4  | 2  | 6  | 12000                    |
| T3                   | 4  | 2  | 8  | 2  | 8000                     |

During planned period it is necessary to produce 18000, 12000 and 8000 vitamin tablets T1, T2 and T3. One kilogram of raw material S1, S2, S3 and S4 one can buy at the market at the price of 16, 24 15 and 20 /mu/. If raw material supplying  $S_j$  has no constraints, one must determine optimal plan of raw materials acquisition with least total expenses.

### Solution

Let  $x_1$ ,  $x_2$ ,  $x_3$  and  $x_4$  represents kilogram number of raw materials S1, S2, S3 and S4, then the model of raw materials acquisition has the form:

$$8 \cdot x_1 + 6 \cdot x_2 + 4 \cdot x_3 + 4 \cdot x_4 = 18000$$

$$4 \cdot x_1 + 4 \cdot x_2 + 2 \cdot x_3 + 6 \cdot x_4 = 12000$$

$$4 \cdot x_1 + 2 \cdot x_2 + 8 \cdot x_3 + 2 \cdot x_4 = 8000$$

The matrix of coefficients and the constraints vector on the basis of the equation system is now:

$$A := \begin{pmatrix} 8 & 6 & 4 & 4 \\ 4 & 4 & 2 & 6 \\ 4 & 2 & 8 & 2 \end{pmatrix}$$

$$B := \begin{pmatrix} 18000 \\ 12000 \\ 8000 \end{pmatrix}$$

ORIGIN := 1

The criterion function is formed as:

$$F(x) := 16 \cdot x_1 + 24 \cdot x_2 + 15 \cdot x_3 + 20 \cdot x_4$$

Where the price vector is:

$$C := (16 \ 24 \ 15 \ 20)$$

One initial value (it is supposed for the last variable):

$$x_4 := 0$$

The block for solving the model of linear programming:

Given

$$A \cdot x = B$$

$$x \geq 0$$

The optimal variants of cutting out bars:

$$X := \text{Minimize } (F, x)$$

so, the optimal values are:

$$X^T = (1250 \ 1000 \ 0 \ 500)$$

The optimal plan presents next values of raw materials quantity /kg/:

$$X_1 = 1250$$

$$X_2 = 1000$$

$$X_3 = 0$$

$$X_4 = 500$$

The minimum aggregate expenses of raw materials acquisition for the production of the planned number of vitamin tablets are /mu/:

$$T := |C \cdot X|$$

$$T = 54000$$

The verification of solution:

$$A \cdot X = \begin{pmatrix} 18000 \\ 12000 \\ 8000 \end{pmatrix}$$

## 1.2 Optimization of production program assortment/quantity [LP3.mcd]

**Example** Production program contains five products [32]: P1, P2, P3, P4 and P5, whose characteristics are given in the table:

$\pi \quad q_i$  – Quantities that can be planned for market /pieces/year/.

$\pi \quad d_j$  – Profit per product unit /dollar/piece/.

T.1.2

| <i>Products</i> |                                 | <i>Units profil <math>d_j</math></i> |
|-----------------|---------------------------------|--------------------------------------|
| <i>P1</i>       | Helical spindle                 | 14                                   |
| <i>P2</i>       | Unit for borders sharpening     | 10                                   |
| <i>P3</i>       | Grindstone spindle              | 7                                    |
| <i>P4</i>       | Universal partitioned apparatus | 12                                   |
| <i>P5</i>       | Distance pads                   | 9                                    |

In the work process analysis for the production of five planned products, besides others, have taken part five kinds of technological systems as like:

- $\pi$  US – universal lathes CNC, with capacity of 50000 hours/year.
- $\pi$  OC – process centres, with capacity of 80000 hours/year.
- $\pi$  BK – coordinative drilling machines, with capacity of 40000 hours/year.
- $\pi$  BR – grinder for flat grinding, with capacity of 50000 hours/year.
- $\pi$  BN – grinder for thread grinding, with capacity of 20000 hours/year.

Here, time standard for products /hours/year/ and given sorts of technological systems is presented in the next table.

T.1.3

| Technological systems | Products |    |    |    |    | Time capacities /hours/ |
|-----------------------|----------|----|----|----|----|-------------------------|
|                       | P1       | P2 | P3 | P4 | P5 |                         |
| US                    | 2        | 5  | 4  | 25 | 10 | 50000                   |
| OC                    | 4        | 25 | 15 | 20 | -  | 80000                   |
| BK                    | 1        | 20 | 5  | 2  | 1  | 40000                   |
| BR                    | 1        | 4  | 10 | 18 | 20 | 50000                   |
| BN                    | 5        | -  | -  | -  | -  | 20000                   |

Production program optimization will be realised in compliance with the above described LP model in which criterion function is given as the need for profit maximization.

System variable:

ORIGIN := 1

Criterion function (profit) is:

$$F(x) := 14 \cdot x_1 + 10 \cdot x_2 + 7 \cdot x_3 + 12 \cdot x_4 + 9 \cdot x_5$$

The constraints defined only by thime capacities of technological systems are:

$$2 \cdot x_1 + 5 \cdot x_2 + 4 \cdot x_3 + 25 \cdot x_4 + 10 \cdot x_5 \leq 50000$$

$$4 \cdot x_1 + 25 \cdot x_2 + 15 \cdot x_3 + 20 \cdot x_4 \leq 80000$$

$$x_1 + 20 \cdot x_2 + 5 \cdot x_3 + 2 \cdot x_4 + x_5 \leq 40000$$

$$x_1 + 4 \cdot x_2 + 10 \cdot x_3 + 18 \cdot x_4 + 20 \cdot x_5 \leq 50000$$

$$5 \cdot x_1 \leq 20000$$

It is necessary to formalize the previous LP model in the form of matrices and vectors as:

The vector of prices:

$$C := (14 \ 10 \ 7 \ 12 \ 9)$$

The matrix of coefficients (operation times) A and constraints vector (time capacities) B:

$$A := \begin{pmatrix} 2 & 5 & 4 & 25 & 10 \\ 4 & 25 & 15 & 20 & 0 \\ 1 & 20 & 5 & 2 & 1 \\ 1 & 4 & 10 & 18 & 20 \\ 5 & 0 & 0 & 0 & 0 \end{pmatrix} \quad B := \begin{pmatrix} 50000 \\ 80000 \\ 40000 \\ 50000 \\ 20000 \end{pmatrix}$$

The solution follows on the basis of the defined model through the matrix A and the vectors B and C, with the supposed initial value (as the last variable in non-equation system):

$$x_5 := 0$$

LP block for solving:

Given

$$A \cdot x \leq B \quad x \geq 0$$

The optimal solution for products quantity:

$$Xr := \text{Maximize}(F, x)$$

$$Xr = \begin{pmatrix} 4000 \\ 1547.61 \\ 453.12 \\ 925.64 \\ 930.84 \end{pmatrix}$$

or apart:

$$Xr_1 = 4000$$

$$Xr_2 = 1547.61$$

$$Xr_3 = 453.12$$

$$Xr_4 = 925.64$$

$$Xr_5 = 930.84$$

The maximal profit is:

$$D := |C \cdot Xr|$$

$$D = 94133.24$$

The verification of arithmetical and logical solution:

$$A \cdot Xr = \begin{pmatrix} 50000 \\ 80000 \\ 40000 \\ 50000 \\ 20000 \end{pmatrix} \quad A \cdot Xr \leq B = \begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{pmatrix} \quad (\text{True})$$

The additional variables are:

$$Xd := A \cdot Xr - B$$

respectively:

$$Xd = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

## 1.4 Linear programming model with two variables [LP4.mcd]

**Example** For the given criterion function and the non-equation system with two unknowns, apply the method of optimum solving of unknown arguments and maximum of criterion function. On the basis of LP model form graphical and animation presentation of the solution.

### Solution

Criterion function (max):  $F(x) := 2 \cdot x_1 + 2 \cdot x_2$  (ORIGIN := 1)

The system of linear constraints:

$$x_1 + 2 \cdot x_2 \leq 8 \quad -x_1 + x_2 \leq 1 \quad -x_1 + 2 \cdot x_2 \geq 0 \quad \frac{4}{5} \cdot x_1 + 2 \cdot x_2 \geq 3$$

On account of equalling relative operators the last two non-equations can be written as:

$$x_1 - 2 \cdot x_2 \leq 0 \quad -\frac{4}{5} \cdot x_1 - 2 \cdot x_2 \leq -3$$

On the basis of previous LP model follows the matrix of coefficients and the constraints vector:

$$A := \begin{pmatrix} 1 & 2 \\ -1 & 1 \\ 1 & -2 \\ -\frac{4}{5} & -2 \end{pmatrix} \quad B := \begin{pmatrix} 8 \\ 1 \\ 0 \\ -3 \end{pmatrix}$$

On the basis of previous LP model, follows the matrix of coefficients and the constraints vector.

The initial value of one unknown (the last variable):  $x_2 := 1$

Block for solving and LP system: Given  $A \cdot x \leq B$   $x \geq 0$

Optimal solution of LP model:  $Xr := \text{Maximize}(F, x)$  so:  $Xr = \begin{pmatrix} 4 \\ 2 \end{pmatrix}$

Maximal value of criterion function is:  $F := |C \cdot Xr|$   $F = 12$

The solution verification:

$$A \cdot Xr = \begin{pmatrix} 8 \\ -2 \\ 0 \\ -7.2 \end{pmatrix} \quad A \cdot Xr - B = \begin{pmatrix} 0 \\ -3 \\ 0 \\ -4.2 \end{pmatrix}$$

The graphical and animation solution of the linear problem:

$$\begin{pmatrix} a \\ b \end{pmatrix} := \begin{pmatrix} 4 \\ 2 \end{pmatrix} \quad Tr := 50 \cdot FRAME$$

**Fig. 1.1** Graphical interpretation of the linear programming model with the presentation of the minimum (zero) and the maximum value of criterion function – profit

## 1.5 Optimization of rocket number [LP5.mcd]

**Example** It is necessary to build a certain AAP (Anti Aircraft Protection) system. It is known that the enemy has 100 planes for the action from low heights, 150 planes for the action from medium heights and 100 planes for the action from great heights, but it is not known from which height will he act. It is possible to provide two types of rockets. The first type of rockets downs planes with possibilities:  $3/4$ ,  $1/2$  and  $1/4$ , and the second type with possibilities:  $1/4$ ,  $1/2$  and  $3/4$ , depending on their flying at low, medium or great heights. The first type costs 25, the second 50 /mu/piece/. How many and which rockets it is necessary to provide so that the expected number of downed planes will not be fewer than the number of planes that can act? Here is necessary the

expenses for acquisition reduce to the minimum possible measure, and to present the solution graphically [20].

### Solution

Criterion function (expenses):                      ORIGIN := 1                       $F(x) := 25 \cdot x_1 + 50 \cdot x_2$

In that case the vector of cost price is:                       $C := (25 \ 50)$

The constraints system concerning number of downed planes:

$$\frac{3}{4} \cdot x_1 + \frac{1}{4} \cdot x_2 \geq 100 \qquad \frac{1}{2} \cdot x_1 + \frac{1}{2} \cdot x_2 \geq 150 \qquad \frac{1}{4} \cdot x_1 + \frac{3}{4} \cdot x_2 \geq 100$$

The matrix of coefficients and constraints vector on the basis of the non-equation system is now:

$$A := \begin{pmatrix} \frac{3}{4} & \frac{1}{4} \\ \frac{1}{2} & \frac{1}{2} \\ \frac{1}{4} & \frac{3}{4} \end{pmatrix} \qquad B := \begin{pmatrix} 100 \\ 150 \\ 100 \end{pmatrix}$$

One initial value (it is supposed for the last variable):                       $x_2 := 0$

The block for solving linear programming model:                      Given

$$A \cdot x \geq B \qquad x \geq 0$$

The optimal rocket quantities:                       $X := \text{Minimize}(F, x)$                        $X = \begin{pmatrix} 250 \\ 50 \end{pmatrix}$

So, for construction an efficient AAP system, it is necessary to provide the next number of rockets:

$$X_1 = 250 \qquad X_2 = 50$$

The minimum value of criterion function is:                       $T := |C \cdot X|$                        $T = 8750$

The verification of solution:                       $A \cdot X = \begin{pmatrix} 200 \\ 150 \\ 100 \end{pmatrix}$

The programming of graphic solution LP and scaling of the x-axis:

$$X := -100 \dots 400$$

$$f(X) := \begin{cases} -3 \cdot X + 400 & \text{if } 0 \leq X \leq 50 \\ -X + 300 & \text{if } 50 \leq X \leq 250 \\ -\frac{1}{3} \cdot X + \frac{400}{3} & \text{if } 250 \leq X \leq 400 \end{cases} \quad \begin{pmatrix} a \\ b \end{pmatrix} := \begin{pmatrix} 250 \\ 50 \end{pmatrix}$$

The bases for the animation realization of criterion function:

$$Tr := 50 \cdot FRAME$$

**Fig. 1.2** The graphical interpretation of linear programming model with the diagram of zero and the minimum value of criterion function – expenses

## 1.6 Raw materials quantity optimization of chemical products [LP6.mcd]

**Example** Chemical industry produces three products P1, P2 and P3 in one separation process from two kinds of raw materials: S1 and S2. On the next table is presented how many tons of products is possible to get out of one ton of raw materials. The factory is obligated to deliver monthly to its partners at least 30, 25 and 20 tons respectively of separate products.

| $S_i \backslash P_j$           | $P1$ | $P2$  | $P3$ |
|--------------------------------|------|-------|------|
| $S1$                           | 0,03 | 0,125 | 0,4  |
| $S2$                           | 0,6  | 0,25  | 0,05 |
| Quantity of products<br>(tons) | 30   | 25    | 20   |

- a) How many tons of raw materials is necessary to supply the commercial department of chemical industry ant the price of 500 and 400 /mu/ respectively, so that the expanses are minimal.
- b) Out of which product we can deliver more to the partners than the lower limit is.
- c) Present in graphical and animation way the solution for the LP model.

### Solution

Constraints system with regard to non-equations: (ORIGIN:= 1)

$$0.03 \cdot x_1 + 0.6 \cdot x_2 \geq 30 \quad 0.125 \cdot x_1 + 0.25 \cdot x_2 \geq 25 \quad 0.4 \cdot x_1 + 0.05 \cdot x_2 \geq 20$$

Criterion function (expenses):  $F(x) := 500 \cdot x_1 + 400 \cdot x_2$

In that case the vector of products price is:  $C := (500 \ 400)$

Matrix of coefficients and constraints vector onthe basis of non-equations system is now:

$$A := \begin{pmatrix} 0.03 & 0.6 \\ 0.125 & 0.25 \\ 0.4 & 0.05 \end{pmatrix} \quad B := \begin{pmatrix} 30 \\ 25 \\ 20 \end{pmatrix}$$

a) One initial value (it is supposed for the last variable):  $x_2 := 0$

The block for solving LP model:

$$\text{Given} \quad A \cdot x \geq B \quad x \geq 0$$

The optimal quantities of P1 and P2 products of the production program:

$$Xr := \text{Minimize}(F, x) \quad \text{or} \quad Xr = \begin{pmatrix} 40 \\ 80 \end{pmatrix}$$

Or separetly:  $Xr_1 = 40 \quad Xr_2 = 80$

The minimum expenses are:  $T := |C \cdot X_r|$   $T = 52000$

Arithmetical and logical verification of the solution:  $A \cdot X_r = \begin{pmatrix} 49.2 \\ 25 \\ 20 \end{pmatrix}$   $A \cdot X_r \geq 0 = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$

b) Possibility for delivery of greater number of products

The additional variables are:  $X_d := A \cdot X_r - B$   $X_d = \begin{pmatrix} 19.2 \\ 0 \\ 0 \end{pmatrix}$

Statement: From P1, the first product to the partners can be delivered for 19.2 tons more than the lower limit of 30 tons is.

Programming low limit of permissible solution:

$$f(X) := \begin{cases} 400 - 8 \cdot X & \text{if } 0 \leq X \leq 40 \\ 100 - \frac{X}{2} & \text{if } 40 \leq X \leq \frac{1000}{9} \\ 50 - \frac{X}{20} & \text{if } \frac{1000}{9} \leq X \leq \infty \end{cases}$$

$$\begin{pmatrix} a \\ b \end{pmatrix} := \begin{pmatrix} 40 \\ 80 \end{pmatrix}$$

$$T_r := 400 \cdot \text{FRAME}$$

**Note** For animation procedures are recommended next parameters: From: 0, To: 130, At: 10 frame/sec.

**Fig. 1.3** Graphical interpretation of linear programming model with the diagram of zero value of criterion function – expenses

## 1.7 Dual model of linear programming [LP7.mcd]

**Example** For known criterion function and non-equation system, form primary and dual LP model. Find out optimal values of unknown arguments and minimal (for primary model) respectively maximal values (for dual model) of criterion function.

### Primary LP model

Criterion function:  $F(x) := 2 \cdot x_0 + 4 \cdot x_1 + 2 \cdot x_2 + 3 \cdot x_3$

$$4 \cdot x_0 + 2 \cdot x_1 + 5 \cdot y_2 + 8 \cdot y_3 \geq 1800$$

Linear constraints system:  $25 \cdot x_0 + 75 \cdot x_1 + 2 \cdot y_2 + 40 \cdot y_3 \geq 2400$

$$16 \cdot x_0 + 10 \cdot x_1 + 7 \cdot y_2 + 4 \cdot y_3 \geq 3000$$

Primary model is described by the next vectors and matrix of coefficients:

$$C := (2 \ 4 \ 2 \ 3) \quad A := \begin{pmatrix} 4 & 2 & 5 & 8 \\ 25 & 75 & 2 & 40 \\ 16 & 10 & 7 & 4 \end{pmatrix} \quad B := \begin{pmatrix} 1800 \\ 2400 \\ 3000 \end{pmatrix}$$

The initial value:  $x_3 := 1$

The block for solving previous LP model: Given

$$A \cdot x \geq B \quad x \geq 0$$

The optimal solution of the LP model:  $Xr := \text{Minimize}(F, x)$

$$Xr = \begin{pmatrix} 53.991 \\ 0 \\ 298.694 \\ 11.321 \end{pmatrix}$$

Minimal value of criterion function is:

$$F := |C \cdot Xr|$$

$$F = 739.33$$

The solution verification:

$$A \cdot Xr = \begin{pmatrix} 1800 \\ 2400 \\ 3000 \end{pmatrix}$$

### $\pi$ Dual LP model

Dual criterion function:

$$\Phi(y) := B^T \cdot y$$

respectively:

$$\Phi(y) := 1800 \cdot y_0 + 2400 \cdot y_1 + 3000 \cdot y_2$$

Linear constraints system:

$$4 \cdot y_0 + 25 \cdot y_1 + 16 \cdot y_2 \leq 2$$

$$5 \cdot y_0 + 2 \cdot y_1 + 7 \cdot y_2 \leq 2$$

$$2 \cdot y_0 + 75 \cdot y_1 + 10 \cdot y_2 \leq 4$$

$$8 \cdot y_0 + 40 \cdot y_1 + 4 \cdot y_2 \leq 3$$

The dual model is described by the next vectors and matrix of coefficients:

$$B^T = (1800 \ 2400 \ 3000) \quad C^T = \begin{pmatrix} 2 \\ 4 \\ 2 \\ 3 \end{pmatrix} \quad A^T = \begin{pmatrix} 4 & 25 & 16 \\ 2 & 75 & 10 \\ 5 & 2 & 7 \\ 8 & 40 & 4 \end{pmatrix}$$

Introductory condition (initial value):

$$y_2 := 1$$

$$\text{Given} \quad A^T \cdot y \leq C^T \quad y \geq 0$$

Block for dual LP model solving:

Optimal solution of LP model:  $Y_r := \text{Maximize}(\Phi, y)$   $Y_r = \begin{pmatrix} 0.35015 \\ 0.00145 \\ 0.0352 \end{pmatrix}$

The maximum value of criterion function is:  $\Phi := |B^T \cdot Y_r|$   $\Phi = 739.33$

Both values are equivalent, i.e.:  $F = \Phi$ , with solution verification:  $A^T \cdot Y_r = \begin{pmatrix} 2 \\ 1.161 \\ 2 \\ 3 \end{pmatrix}$

## 2. TRANSPORTATION PROBLEM

### 2.1 Transportation problem with minimal expenses [TP1.mcd]

**Example** For needs of three industrial centres, there is imported one sort of material from three different countries, according to offer and request [23]:

Offer:  $P := \begin{pmatrix} 6000 \\ 8000 \\ 3000 \end{pmatrix}$   $\sum P = 17000$  Request:  $T := \begin{pmatrix} 5000 \\ 2000 \\ 10000 \end{pmatrix}$   $\sum T = 17000$

Transportation costs per import unit are given in the next table:

T.2.1

| <i>Centre</i><br><i>Country</i> | <i>I</i>     | <i>II</i>    | <i>III</i>   | <i>Offer</i>     |
|---------------------------------|--------------|--------------|--------------|------------------|
| <i>A</i>                        | 2<br>$x_1=?$ | 7<br>$x_2=?$ | 5<br>$x_3=?$ | 6000             |
| <i>B</i>                        | 3<br>$x_4=?$ | 1<br>$x_5=?$ | 4<br>$x_6=?$ | 8000             |
| <i>C</i>                        | 5<br>$x_7=?$ | 3<br>$x_8=?$ | 7<br>$x_9=?$ | 3000             |
| <i>Request</i>                  | 5000         | 2000         | 10000        | $\Sigma = 17000$ |

Or through costs vector:

$$C := (2 \ 7 \ 5 \ 3 \ 1 \ 4 \ 5 \ 3 \ 7)$$

- Find initial transport program.
- Define optimal transport program so that total transportation (import) costs would be minimal.

### Solution

According to given elements, transport problem can be expressed by costs function:

$$F(x) := 2 \cdot x_0 + 7 \cdot x_1 + 5 \cdot x_2 + 3 \cdot x_3 + x_4 + 4 \cdot x_5 + 5 \cdot x_6 + 3 \cdot x_7 + 7 \cdot x_8$$

And coefficients matrix and constraints vector on the basis of equations system:

$$M := \begin{pmatrix} 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 \\ 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 \end{pmatrix} \quad V := \text{stack}(P, T) \quad V = \begin{pmatrix} 6000 \\ 8000 \\ 3000 \\ 5000 \\ 2000 \\ 10000 \end{pmatrix}$$

As total of offers is equal to total of requests, this problem is of closed type:

$$\sum P = \sum T = 1 \quad (\text{true})$$

One initial solution value of one (last) variable:  $x_8 := 0$

Block for solving linear programming model: Given

Linear equations system:  $M \cdot x = V \quad x \geq 0$

Optimal quantities of transport quantities X:

$$X := \text{Minimize}(F, x) \quad X = \begin{pmatrix} 5000 \\ 0 \\ 1000 \\ 0 \\ 0 \\ 8000 \\ 0 \\ 2000 \\ 1000 \end{pmatrix}$$

Minimum system costs:  $Tr := |C \cdot Xr| \quad Tr = 60000$

Values of optimal transport:  $\begin{pmatrix} X_0 & X_1 & X_2 \\ X_3 & X_4 & X_5 \\ X_6 & X_7 & X_8 \end{pmatrix} = \begin{pmatrix} 5000 & 0 & 1000 \\ 0 & 0 & 8000 \\ 0 & 2000 & 1000 \end{pmatrix}$

LP solution verifikation:

$$M \cdot X = \begin{pmatrix} 6000 \\ 8000 \\ 3000 \\ 5000 \\ 2000 \\ 10000 \end{pmatrix}$$

## 2.2 Transport task with minimal expenses [TP2.mcd]

**Example** For needs of three business centres they import one sort of material from three various regions according to offer and request. Transport expenses per import unit are given in the next table.

T.2.2

| <i>Centre<br/>Region</i> | $C_1$ (17)                                   | $C_2$ (21)                                   | $C_3$ (41)                                  | $C_4$ (14)                                  | $C_5$ (24)                                  |
|--------------------------|--|--|---|---|---|
| $R_1$ (25)               | $\begin{matrix} 10 \\ x_1=? \end{matrix}$    | $\begin{matrix} 8 \\ x_2=? \end{matrix}$     | $\begin{matrix} 9 \\ x_3=? \end{matrix}$    | $\begin{matrix} 6 \\ x_4=? \end{matrix}$    | $\begin{matrix} 5 \\ x_5=? \end{matrix}$    |
| $R_2$ (32)               | $\begin{matrix} 5 \\ x_6=? \end{matrix}$     | $\begin{matrix} 6 \\ x_7=? \end{matrix}$     | $\begin{matrix} 4 \\ x_8=? \end{matrix}$    | $\begin{matrix} 3 \\ x_9=? \end{matrix}$    | $\begin{matrix} 8 \\ x_{10}=? \end{matrix}$ |
| $R_3$ (40)               | $\begin{matrix} 9 \\ x_{11}=? \end{matrix}$  | $\begin{matrix} 7 \\ x_{12}=? \end{matrix}$  | $\begin{matrix} 6 \\ x_{13}=? \end{matrix}$ | $\begin{matrix} 4 \\ x_{14}=? \end{matrix}$ | $\begin{matrix} 3 \\ x_{15}=? \end{matrix}$ |
| $R_4$ (20)               | $\begin{matrix} 14 \\ x_{16}=? \end{matrix}$ | $\begin{matrix} 10 \\ x_{17}=? \end{matrix}$ | $\begin{matrix} 8 \\ x_{18}=? \end{matrix}$ | $\begin{matrix} 8 \\ x_{19}=? \end{matrix}$ | $\begin{matrix} 8 \\ x_{20}=? \end{matrix}$ |

- Find initial transport program.
- Determine optimal transport program, so that total transport expenses would be minimal.

Prices vector is formed on the basis of Matrix tool palette, through direct input of data:

$$C := (10 \ 8 \ 9 \ 6 \ 5 \ 5 \ 6 \ 4 \ 3 \ 8 \ 9 \ 7 \ 6 \ 4 \ 3 \ 14 \ 10 \ 8 \ 8 \ 8)$$

According to given elements, transport problem can be expressed in the form of expenses function (criterion):

$$\text{ORIGIN} := 1 \quad n := 1..20 \quad F(x) := \sum_n (C^T)_n \cdot x_n$$

With adequate matrix of coefficients and constraints vector in view of equations system. The matrix of coefficients for constraint per region capacity is:

$$P := \begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 \end{pmatrix}$$

Matrix of coefficients for constraint per centre capacity is:

$$S := \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}$$

We get complete matrix as a connected serie:

$$A := \text{stack}(P, S)$$

A =

|   | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 |
|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|
| 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 2 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 3 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 1  | 1  | 1  | 1  | 1  | 0  | 0  | 0  | 0  | 0  |
| 4 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 1  | 1  | 1  | 1  |
| 5 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  |
| 6 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  |
| 7 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  |
| 8 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  |
| 9 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  |

The constraints vector in regions and centres is:

$$B := \begin{pmatrix} 25 \\ 32 \\ 40 \\ 20 \\ 17 \\ 21 \\ 41 \\ 14 \\ 24 \end{pmatrix}$$

One initial value (of the last member):

$$x_{20} := 0$$

Block for solving linear programming model:

Given

Linear equations system:

$$A \cdot x = B$$

$$x \geq 0$$

Optimal transport quantities:

$$X := \text{Minimize}(F, x)$$

$$X^T = (0 \ 21 \ 0 \ 0 \ 4 \ 17 \ 0 \ 15 \ 0 \ 0 \ 0 \ 0 \ 6 \ 14 \ 20 \ 0 \ 0 \ 20 \ 0 \ 0)$$

Minimal transport expenses are:

$$T := |C \cdot X|$$

$$T = 645$$

The values of optimal transport plan can be presented through matrix:

$$\begin{pmatrix} X_1 & X_2 & X_3 & X_4 & X_5 \\ X_6 & X_7 & X_8 & X_9 & X_{10} \\ X_{11} & X_{12} & X_{13} & X_{14} & X_{15} \\ X_{16} & X_{17} & X_{18} & X_{19} & X_{20} \end{pmatrix} = \begin{pmatrix} 0 & 21 & 0 & 0 & 4 \\ 17 & 0 & 15 & 0 & 0 \\ 0 & 0 & 6 & 14 & 20 \\ 0 & 0 & 20 & 0 & 0 \end{pmatrix}$$

Solution verifikation:  $(A \cdot X)^T = (25 \ 32 \ 40 \ 20 \ 17 \ 21 \ 41 \ 14 \ 24)$

or:  $A \cdot X = B = 1 \quad (\text{true})$

## 2.3 Transport problem of profit maximum [TP3.mcd]

**Example** Electronic industry in its basic for organisations during a month should produce 72000 product units. For this product ought to be found market in four consumer centres. Earnings per product unit depends on production place and placemnet place. Every plant produces 18000 product units. Market analysis has indicated that consumer centres P1, P2, P3 and P4 need 8000, 12000, 20000, 32000 units, respectively [20]. This analysis and transport conditions showed that earnings per product unit is as it is given in the table.

T.2.3

| <i>Centre</i><br><i>Plant</i> | C1 (8000)       | C2 (12000)      | C3 (20000)      | C4 (32000)      |
|-------------------------------|-----------------|-----------------|-----------------|-----------------|
| P1 (18000)                    | 10 / $y_1=?$    | 50 / $y_2=?$    | 80 / $y_3=?$    | 30 / $y_4=?$    |
| P2 (18000)                    | 10 / $y_5=?$    | 60 / $y_6=?$    | 40 / $y_7=?$    | 50 / $y_7=?$    |
| P3 (18000)                    | 80 / $y_8=?$    | 90 / $y_9=?$    | 20 / $y_{10}=?$ | 70 / $y_{11}=?$ |
| P4 (18000)                    | 40 / $y_{12}=?$ | 60 / $y_{13}=?$ | 50 / $y_{14}=?$ | 20 / $y_{15}=?$ |

It is necessary to determine distribution of products in consumer centres, that will enable the greatest earnings and optimal transport values.

### Solution

The vector of earnings value is brought in view of table data:

$$C := (40 \ 50 \ 80 \ 30 \ 10 \ 60 \ 40 \ 50 \ 80 \ 90 \ 20 \ 70 \ 40 \ 60 \ 50 \ 20)$$

According to given elements, transport problem can be expressed in the form of profit function:

$$n := 0..15 \quad D(y) := \sum_n (c^T)_n \cdot y_n$$

And appropriate constraints as linear equations:

$$y_0 + y_1 + y_3 + y_4 + 0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 = 18000$$

$$0 + 0 + 0 + 0 + y_5 + y_6 + y_7 + y_8 + 0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 = 18000$$

$$0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 + y_9 + y_{10} + y_{11} + y_{12} + 0 + 0 + 0 + 0 + 0 = 18000$$

$$0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 + y_{12} + y_{13} + y_{14} + y_{15} = 18000$$

$$y_0 + 0 + 0 + 0 + y_4 + 0 + 0 + 0 + y_8 + 0 + 0 + 0 + y_{12} + 0 + 0 + 0 = 8000$$

$$0 + y_1 + 0 + 0 + 0 + y_5 + 0 + 0 + 0 + y_9 + 0 + 0 + 0 + y_{13} + 0 + 0 = 12000$$

$$0 + 0 + y_2 + 0 + 0 + 0 + y_6 + 0 + 0 + 0 + y_{10} + 0 + 0 + 0 + y_{14} + 0 = 20000$$

$$0 + 0 + 0 + y_3 + 0 + 0 + 0 + y_7 + 0 + 0 + 0 + y_{11} + 0 + 0 + 0 + y_{15} = 32000$$

**Advice** Forming the previous system of constraints equations is not indispensably for solving transport problem, in contrast to bringing in the next expressions that refer to the vectors C and B and the matrix A.

The complete matrix of coefficients is formed by opening and filling in blank table. We have got the Input Table through the dialogue of Component Wizard from the menu Insert ○ Component. The reason for table forming is that we can not form a matrix with more than 100 elements through the Insert Matrix procedure from the toolbar Matrix.

A :=

|   | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
|---|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|
| 0 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  |
| 1 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  |
| 2 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1  | 1  | 0  | 0  | 0  | 0  |
| 3 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 1  | 1  | 1  | 1  |
| 4 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0  | 0  | 1  | 0  | 0  | 0  |
| 5 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 0  | 0  | 0  | 1  | 0  | 0  |
| 6 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1  | 0  | 0  | 0  | 1  | 0  |
| 7 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0  | 1  | 0  | 0  | 0  | 1  |

Constraints vector by regions and centres:

$$B := \begin{pmatrix} 18000 \\ 18000 \\ 18000 \\ 18000 \\ 8000 \\ 12000 \\ 20000 \\ 32000 \end{pmatrix}$$

One initial value:

$$y_{15} := 2$$

Block for solving linear programming:

Given

Linear equations system:

$$A \cdot y = B$$

$$y \geq 0$$

Optimal quantities of transport quantities Y:

$$Y := \text{Maximize}(D, y)$$

$$Y^T = (0 \ 0 \ 18000 \ 0 \ 0 \ 0 \ 0 \ 18000 \ 4000 \ 0 \ 0 \ 14000 \ 4000 \ 12000 \ 2000 \ 0)$$

Maximum company profit is:

$$Pr := |C \cdot Y|$$

$$Pr = 4620000$$

The value of optimal transport plan, arranged as the matrix 4x4:

$$\begin{pmatrix} Y_0 & Y_1 & Y_2 & Y_3 \\ Y_4 & Y_5 & Y_6 & Y_7 \\ Y_8 & Y_9 & Y_{10} & Y_{11} \\ Y_{12} & Y_{13} & Y_{14} & Y_{15} \end{pmatrix} = \begin{pmatrix} 0 & 0 & 18000 & 0 \\ 0 & 0 & 0 & 18000 \\ 4000 & 0 & 0 & 14000 \\ 4000 & 12000 & 2000 & 0 \end{pmatrix}$$

Solution verifikation:

$$(A \cdot Y)^T = (18000 \ 18000 \ 18000 \ 18000 \ 8000 \ 12000 \ 20000 \ 32000)$$

## 2.4 Transport problem of profit maximum [TP4.mcd]

**Example** A great agricultural combine has classified its land in view of its structure into six categories and also gave been determined both dimensions of land complexes that belong to single categories, as well yields of 7 main products in /mu/ per land registry acre of categorized land. The next table presents the obtained data [7]:

T.2.4

| $K_i \backslash P_j$ | Wheat | Oat   | Oet  | Maize | Abfalfa | Potato | Turnip | Complex /a/ |
|----------------------|-------|-------|------|-------|---------|--------|--------|-------------|
| K1                   | 12    | 18    | 5    | 0     | 20      | 100    | 60     | 4000        |
| K2                   | 8     | 14    | 3    | 40    | 10      | 120    | 0      | 8000        |
| K3                   | 18    | 5     | 5    | 36    | 16      | 60     | 0      | 14000       |
| K4                   | 16    | 12    | 0    | 50    | 4       | 0      | 140    | 2000        |
| K5                   | 4     | 0     | 8    | 25    | 0       | 40     | 230    | 18000       |
| K6                   | 5     | 24    | 0    | 42    | 18      | 80     | 200    | 23000       |
| Plan /a/             | 20000 | 16000 | 2000 | 24000 | 3000    | 1000   | 3000   | 69000       |

In accordance with sowing plan it is foreseen that with single sulture will be sown respectively 20000, 16000, 2000, 24000, 3000, 1000 and 3000 land registry acres (a). Which sowing plan should be realized, if the aim is maximizing production quantity?

### Solution

Vector of Prices is brought in in view of table data:

ORIGIN := 1

C :=

|   | 1  | 2  | 3 | 4 | 5  | 6   | 7  | 8 | 9  | 10 | 11 | 12 | 13  | 14 | 15 |
|---|----|----|---|---|----|-----|----|---|----|----|----|----|-----|----|----|
| 1 | 12 | 18 | 5 | 0 | 20 | 100 | 60 | 8 | 14 | 3  | 40 | 10 | 120 | 0  | 18 |

According to given elements, transport problem can be expressed in form of profit function:

$$n := 1 \dots 42 \quad D(q) := \sum_n (C^T)_n \cdot q_n$$

And appropriate constraints in form of linear equations

Complete matrix of coefficientst is formed by opening and filling in blank of the table. We get Input Table through the dialogue of Component Wizard from the menu Insert ○ Component.

A :=

|    | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 |
|----|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 2  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1  | 1  | 1  | 1  | 1  | 0  | 0  | 0  | 0  | 0  | 0  |
| 3  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 1  | 1  | 1  | 1  | 1  | 1  |
| 4  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

| 6  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 7  | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 0  |
| 8  | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  |
| 9  | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  |
| 10 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0  | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 0  | 0  |
| 11 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 0  |
| 12 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 1  |
| 13 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 0  | 0  |

Constraints vector by regions and centres:

B :=

|   | 1     |
|---|-------|
| 1 | 4000  |
| 2 | 8000  |
| 3 | 14000 |
| 4 | 2000  |
| 5 | 18000 |
| 6 | 23000 |
| 7 | 20000 |
| 8 | 16000 |

One initial value (last):

$$q_{42} := 0$$

Block for solving models of linear programming:      Given

Linear equations system:

$$A \cdot q = B$$

$$q \geq 0$$

Optimal quantities of transport quantities:

$$Q := \text{Minimize}(D, q)$$

$$Q^T =$$

|   | 1 | 2 | 3 | 4    | 5 | 6 | 7 | 8 | 9    | 10 | 11   | 12   | 13 | 14   | 15 |
|---|---|---|---|------|---|---|---|---|------|----|------|------|----|------|----|
| 1 | 0 | 0 | 0 | 4000 | 0 | 0 | 0 | 0 | 2000 | 0  | 1000 | 2000 | 0  | 3000 | 0  |

Maximum company profit is:

$$Pr := |C \cdot Q|$$

$$Pr = 754000$$

The value of optimal transport plan, arranged as matrix 6x7:

$$\begin{pmatrix} Q_1 & Q_2 & Q_3 & Q_4 & Q_5 & Q_6 & Q_7 \\ Q_8 & Q_9 & Q_{10} & Q_{11} & Q_{12} & Q_{13} & Q_{14} \\ Q_{15} & Q_{16} & Q_{17} & Q_{18} & Q_{19} & Q_{20} & Q_{21} \\ Q_{22} & Q_{23} & Q_{24} & Q_{25} & Q_{26} & Q_{27} & Q_{28} \\ Q_{29} & Q_{30} & Q_{31} & Q_{32} & Q_{33} & Q_{34} & Q_{35} \\ Q_{36} & Q_{37} & Q_{38} & Q_{39} & Q_{40} & Q_{41} & Q_{42} \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 & 4000 & 0 & 0 & 0 \\ 0 & 2000 & 0 & 1000 & 2000 & 0 & 3000 \\ 0 & 14000 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1000 & 1000 & 0 \\ 0 & 0 & 0 & 18000 & 0 & 0 & 0 \\ 20000 & 0 & 2000 & 1000 & 0 & 0 & 0 \end{pmatrix}$$

Solution verification:

$$(A \cdot Q)^T =$$

|   | 1    | 2    | 3     | 4    | 5     | 6     | 7     | 8     | 9    | 10    | 11   | 12   | 13   |

| 1 | 4000 | 8000 | 14000 | 2000 | 18000 | 23000 | 20000 | 16000 | 2000 | 24000 | 3000 | 1000 | 3000 |

**Note** Look at the contents of TP4\_1.mcd file, where the resulting matrix is program solved.

## 2.5 Transport problem of minimum expenses [TP5.mcd]

**Example** In the following table are given goods quantities necessary to be dispatched from forwarding stations FS, goods quantities wanted in admission stations AS, as well transport prices from every forwarding station to every admission station.

T.2.5

| <i>OC \ PS</i>                | <i>B1</i> | <i>B2</i> | <i>B3</i> | <i>B4</i> | <i>B5</i> | <i>Goods quantity /piece/</i> |
|-------------------------------|-----------|-----------|-----------|-----------|-----------|-------------------------------|
| <i>A1</i>                     | 5         | 12        | 1         | 4         | 13        | 36                            |
| <i>A2</i>                     | 7         | 8         | 14        | 6         | 5         | 23                            |
| <i>A3</i>                     | 15        | 4         | 2         | 7         | 9         | 29                            |
| <i>A4</i>                     | 6         | 11        | 5         | 16        | 3         | 12                            |
| <i>Goods quantity /piece/</i> | 13        | 24        | 15        | 21        | 27        | $\Sigma=100$                  |

Which transport plan to be realized if the objective is minimizing of total transport expenses?

**Solution**

Vector of prices is brought in in view of table data:

(ORIGIN:= 1)

C :=

|   | 1 | 2  | 3 | 4 | 5  | 6 | 7 | 8  | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
|---|---|----|---|---|----|---|---|----|---|----|----|----|----|----|----|----|
| 1 | 5 | 12 | 1 | 4 | 13 | 7 | 8 | 14 | 6 | 5  | 15 | 4  | 2  | 7  | 9  | 6  |

According to given elements, transport problem can be expressed in the form of profit function:

$$n := 1..20 \quad T(x) := \sum_n (C^T)_n \cdot x_n$$

And adequate constraints in form of linear equations.

Complete matrix of coefficients is formed by opening and filling in blank table. We get Input Table through the dialogue Component Wizard from the menu Insert  $\square$  Component.

A :=

|   | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 |
|---|---|---|---|---|---|---|---|---|---|----|----|----|----|
| 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  |
| 2 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1  | 0  | 0  | 0  |
| 3 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 1  | 1  | 1  |
| 4 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  |
| 5 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0  | 1  | 0  | 0  |
| 6 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0  | 0  | 1  | 0  |
| 7 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0  | 0  | 0  | 1  |
| 8 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0  | 0  | 0  | 0  |
| 9 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1  | 0  | 0  | 0  |

Constraint vector by regions and centres:

B :=

|   | 1  |
|---|----|
| 1 | 36 |
| 2 | 23 |
| 3 | 29 |
| 4 | 12 |
| 5 | 13 |
| 6 | 24 |
| 7 | 15 |
| 8 | 21 |
| 9 | 27 |

One initial value (the last one):

$$x_{20} := 0$$

Block for solving linear programming model:

Given

Linear equations system:

$$A \cdot x = B \quad x \geq 0$$

Optimal quantities of transport quantities q:

$$q := \text{Minimize}(T, x)$$

$$q^T = (5 \ 0 \ 10 \ 21 \ 0 \ 8 \ 0 \ 0 \ 0 \ 15 \ 0 \ 24 \ 5 \ 0 \ 0 \ 0 \ 0 \ 0 \ 12)$$

Minimum expenses are:

$$Tr := |C \cdot q| \quad Tr = 392$$

The values of optimal transport plan, arranged as 4x5 matrix:

$$\begin{pmatrix} q_1 & q_2 & q_3 & q_4 & q_5 \\ q_6 & q_7 & q_8 & q_9 & q_{10} \\ q_{11} & q_{12} & q_{13} & q_{14} & q_{15} \\ q_{16} & q_{17} & q_{18} & q_{19} & q_{20} \end{pmatrix} = \begin{pmatrix} 5 & 0 & 10 & 21 & 0 \\ 8 & 0 & 0 & 0 & 15 \\ 0 & 24 & 5 & 0 & 0 \\ 0 & 0 & 0 & 0 & 12 \end{pmatrix}$$

Solution verification:  $(A \cdot q)^T = (36 \ 23 \ 29 \ 12 \ 13 \ 24 \ 15 \ 21 \ 27)$

## 2.6 Transport problem of minimum of expenses [TP6.mcd]

**Example** For needs of seven business centres they import a sort of material from eight various countries according to offer and request (T.2.6). Transport expenses per import unit are given in the next table.

T.2.6

| <i>Centre<br/>Country</i> | <i>P1</i>     | <i>P2</i>     | <i>P3</i>     | <i>P4</i>     | <i>P5</i>     | <i>P6</i>     | <i>P7</i>     | <i>Offer</i>   |
|---------------------------|---------------|---------------|---------------|---------------|---------------|---------------|---------------|----------------|
| <i>S1</i>                 | 1 $x_1=?$     | 3 $x_2=?$     | 5 $x_3=?$     | 7 $x_4=?$     | 9 $x_5=?$     | 11 $x_6=?$    | 8 $x_7=?$     | 300            |

- Find initial transport program.
- Determine optimal transport program so that total transport expenses are minimal.

Vector of prices is formed in view of Matrix toolbar through direct bringing in data:

C :=

|   | 0 | 1 | 2 | 3 | 4 | 5  | 6 | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 |
|---|---|---|---|---|---|----|---|----|----|----|----|----|----|----|----|
| 0 | 1 | 3 | 5 | 7 | 9 | 11 | 8 | 14 | 12 | 10 | 6  | 8  | 6  | 3  | 7  |

According to given elements, transport problem can be expressed in the form of expenses function (criterion):

$$\text{ORIGIN} := 1 \quad n := 1 \dots 56 \quad F(x) := \sum_n (C^T)_n \cdot x_n$$

With appropriate matrix of coefficients and constraints vector in view of system of equations. The matrix of coefficients for constraint for region capacities is:

A :=

|   | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|
| 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 2 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1  | 1  | 1  | 1  | 1  | 0  | 0  |
| 3 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 1  | 1  |
| 4 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 5 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 6 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 7 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

Number of elements in matrix:  $s := (\text{last}(A^{<1>}) + 1) \cdot [\text{last}[(A^T)^{<1>}] + 1]$   $s = 912$

Constraints vector for regions and centres is:

B :=

|   | 1   |
|---|-----|
| 1 | 300 |
| 2 | 290 |
| 3 | 280 |
| 4 | 270 |
| 5 | 260 |
| 6 | 250 |
| 7 | 240 |
| 8 | 230 |

One initial value (the last one):  $x_{56} := 0$

Block for solving the model of linear programming: Given

System of linear equations:  $A \cdot x = B$   $x \geq 0$

Optimal transport quantities:  $X := \text{Minimize}(F, x)$

$x^T =$

|   | 1 | 2  | 3 | 4  | 5   | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13  | 14 |
|---|---|----|---|----|-----|---|---|---|---|----|----|----|-----|----|
| 1 | 0 | 10 | 0 | 80 | 210 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 290 | 0  |

Minimum transport expenses are:  $T := |C \cdot X|$   $T = 14560$

Values of optimal transport plan can be presented through matrix:

$$\begin{pmatrix} x_1 & x_2 & x_3 & x_4 & x_5 & x_6 & x_7 \\ x_8 & x_9 & x_{10} & x_{11} & x_{12} & x_{13} & x_{14} \\ x_{15} & x_{16} & x_{17} & x_{18} & x_{19} & x_{20} & x_{21} \\ x_{22} & x_{23} & x_{24} & x_{25} & x_{26} & x_{27} & x_{28} \\ x_{29} & x_{30} & x_{31} & x_{32} & x_{33} & x_{34} & x_{35} \\ x_{36} & x_{37} & x_{38} & x_{39} & x_{40} & x_{41} & x_{42} \\ x_{43} & x_{44} & x_{45} & x_{46} & x_{47} & x_{48} & x_{49} \\ x_{50} & x_{51} & x_{52} & x_{53} & x_{54} & x_{55} & x_{56} \end{pmatrix} = \begin{pmatrix} 0 & 10 & 0 & 80 & 210 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 290 & 0 \\ 170 & 110 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 190 & 0 & 0 & 80 & 0 \\ 0 & 0 & 0 & 0 & 0 & 20 & 240 \\ 0 & 0 & 0 & 250 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 50 & 0 & 190 \\ 0 & 0 & 0 & 0 & 230 & 0 & 0 \end{pmatrix}$$

Solution verification:

$$(A \cdot X)^T = \begin{array}{c|cccccccccc} & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\ \hline 1 & 300 & 290 & 280 & 270 & 260 & 250 & 240 & 230 & 170 & 120 \end{array}$$

## 2.7 Transport problem of minimum expenses [TP7.mcd]

**Example** Three mills (M1, M2 and M3) supplying with flour three bakery companies (P1, P2 and P3). In the next month the mills can produce 750, 400 and 350 tons of flour, respectively. In the same period the bakery companies should get: 75, 40 and 35 tons of flour respectively. Transport expenses per ton of flour from mill to baker's companies are: from the first mill 70, 30 and 60 /mu/ per Pj company respectively, from the second mill 40, 80 and 20 /mu/ per Pj company respectively and from the third mill 10, 50 and 90 /mu/ per Pj company respectively (T.2.7).

T.2.7

| <i>Bakeries</i><br><i>Mills</i>    | <i>P1</i>    | <i>P2</i>    | <i>P3</i>    | <i>Capacities of<br/>bakeries /t/</i> |
|------------------------------------|--------------|--------------|--------------|---------------------------------------|
| <i>M1</i>                          | 70 / $x_1=?$ | 30 / $x_2=?$ | 60 / $x_3=?$ | $a_1=75$                              |
| <i>M2</i>                          | 40 / $x_4=?$ | 80 / $x_5=?$ | 20 / $x_6=?$ | $a_2=40$                              |
| <i>M3</i>                          | 10 / $x_7=?$ | 50 / $x_8=?$ | 90 / $x_9=?$ | $a_3=35$                              |
| <i>Capacities of<br/>mills /t/</i> | $b_1=20$     | $b_2=45$     | $b_3=30$     | $\Sigma=150$<br>$\Sigma=95$           |

Find optimal transport plan, to which will suit minimal expenses.

### Solution

Mathematical model is formed in order to determine open transport problem where we ought to determine value of non-negative variables  $x_{ij}$ . Here are initial parameters:

Number of rows:  $m := 3$       number of columns:  $n := 3$       (ORIGIN := 1)

Index values:       $i := 1..3$        $j := 1..3$

Capacities in vector form:       $a := \begin{pmatrix} 75 \\ 40 \\ 35 \end{pmatrix}$        $b := \begin{pmatrix} 20 \\ 45 \\ 30 \end{pmatrix}$

Sum of capacities:       $\sum a = 150$        $\sum b = 95$        $\sum a \neq \sum b$

And it is open transport problem. Because request is greater than offer, we bring in a fictitious bakery P4 with the capacity:

$$b_4 := \sum a - \sum b \quad \text{follows that:} \quad b_4 = 0$$

Capacities in expanded vector are:       $a := \begin{pmatrix} 75 \\ 40 \\ 35 \end{pmatrix}$        $b := \begin{pmatrix} 20 \\ 45 \\ 30 \\ b_4 \end{pmatrix}$

T.2.8

| <i>Bakeries</i><br><i>Mills</i>          | <i>P1</i>    | <i>P2</i>    | <i>P3</i>    | <i>P4</i>      | <i>Capacities of</i><br><i>bakeries /t/</i> |
|--|--------------|--------------|--------------|----------------|---|
| <i>M1</i>                                | 70 / $x_1=?$ | 30 / $x_2=?$ | 60 / $x_3=?$ | 0 / $x_4=?$    | $a_1=75$                                    |
| <i>M2</i>                                | 40 / $x_4=?$ | 80 / $x_5=?$ | 20 / $x_6=?$ | 0 / $x_8=?$    | $a_2=40$                                    |
| <i>M3</i>                                | 10 / $x_7=?$ | 50 / $x_8=?$ | 90 / $x_9=?$ | 0 / $x_{12}=?$ | $a_3=35$                                    |
| <i>Capacities of</i><br><i>mills /t/</i> | $b_1=20$     | $b_2=45$     | $b_3=30$     | $b_4=55$       | $\Sigma=150$<br>$\Sigma=95$                 |

Vector of expenses value is formed through direct data input from the expanded table T.2.8:

$$C := (70 \ 30 \ 60 \ 0 \ 40 \ 80 \ 20 \ 0 \ 10 \ 50 \ 90 \ 0)$$

According to the given elements, transport problem can be expressed in form of expenses function (criterion):

$$k := 1..(n+1) \cdot m \quad F(x) := \sum_k (C^T)_k \cdot x_k$$

With adequate matrix of coefficients and constraints vector in view of equations system. The matrix of coefficients for constraint for all capacities is:

A :=

|   | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
|---|---|---|---|---|---|---|---|---|---|----|----|----|
| 2 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 0 | 0  | 0  | 0  |
| 3 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1  | 1  | 1  |
| 4 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 0  | 0  | 0  |
| 5 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1  | 0  | 0  |
| 6 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0  | 1  | 0  |

Constraints vector for capacities is:

B := stack (a, b)

$$B = \begin{pmatrix} 75 \\ 40 \\ 35 \\ 20 \\ 45 \\ 30 \\ 0 \end{pmatrix}$$

One initial value (the last one):

$$x_{12} := 0$$

Block for solving linear programming model:

Given

Linear equations system:

$$A \cdot x = B$$

$$x \geq 0$$

Optimal transport quantities X:

$$X := \text{Minimize}(F, x)$$

$$X^T = (0 \ 45 \ 0 \ 30 \ 0 \ 0 \ 30 \ 10 \ 20 \ 0 \ 0 \ 15)$$

Minimum transport expenses are:

$$T := |C \cdot X|$$

$$T = 2150$$

Values of optimal transport plan can be presented through matrix:

$$\begin{pmatrix} X_1 & X_2 & X_3 & X_4 \\ X_5 & X_6 & X_7 & X_8 \\ X_9 & X_{10} & X_{11} & X_{12} \end{pmatrix} = \begin{pmatrix} 0 & 45 & 0 & 30 \\ 0 & 0 & 30 & 10 \\ 20 & 0 & 0 & 15 \end{pmatrix}$$

Arithmetical and logical solution verification:

$$A \cdot X = \begin{pmatrix} 75 \\ 40 \\ 35 \\ 20 \\ 45 \\ 30 \\ 55 \end{pmatrix}$$

and

$$A \cdot X = B = 1 \quad (\text{true}).$$

### 3. ASSIGNMENTS PROBLEMS

#### 3.1 Employees assignment [AP1a.mcd]

**Example** Production system in which are being manufactured final products from wood has advertised an vacancy for 5 macnihe carpenters for 5 working places (planer, milling machine, lathe, loring machine, grinder). After analyzing registration forms for the competition, all appointed conditions have been satisfied by five candidates. In order to space workers evenly to working places, there was organized probation [30]. Each candidate has got to process 100 same pieces on every machine and then was found a number of good pieces that was spoilage (T.3.1). The assignment was to dispose workers on working places, and that will provide minimal total spoilage.

T.3.1

| Workers | Number of points |    |    |    |    |
|---------|------------------|----|----|----|----|
|         | P1               | P2 | P3 | P4 | P5 |
| R1      | 3                | 21 | 12 | 6  | 10 |
| R2      | 8                | 23 | 2  | 5  | 5  |
| R3      | 33               | 14 | 13 | 10 | 7  |
| R4      | 14               | 21 | 19 | 11 | 11 |
| R5      | 9                | 16 | 10 | 15 | 13 |

#### Solution

Values vector of non-standard (bad) products:

ORIGIN := 1

Criterion function, as function of minimal spoilages:

n := 5

m := 5

C :=

|   | 1 | 2  | 3  | 4 | 5  | 6 | 7  | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 |
|---|---|----|----|---|----|---|----|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1 | 3 | 21 | 12 | 6 | 10 | 8 | 23 | 2 | 5 | 5  | 33 | 14 | 13 | 10 | 7  | 14 | 21 | 19 | 11 | 11 | 9  | 16 | 10 | 15 | 13 |

Criterion function, as function of minimal spoilages:

$$j := 1 \dots n \cdot m \qquad D(x) := \sum_{j=1}^{n \cdot m} (C^T)_j \cdot x_j$$

Complete matrix of constraints is formed by opening and filling in blank table. Input table has been got through Component wizard dialoge from Insert ○ Component menu.

Table A size:

$$(n + m) \cdot n \cdot m = 250$$

Vector B size:

$$m + n = 10$$

A :=

|    | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 |
|----|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 2  | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 3  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 1  | 1  | 1  | 1  | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 4  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 1  | 1  | 1  | 1  | 0  | 0  | 0  | 0  | 0  |
| 5  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 1  | 1  | 1  | 1  |
| 6  | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  |
| 7  | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  |
| 8  | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  |
| 9  | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  |
| 10 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  |

Constraints vector that defines possibility that only one worker can work at one machine and that only one work can be assigned to one worker:

$$B := \begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{pmatrix}$$

One initial value (the last one):  $x_{25} := 0$

Block for solving linear programming model: Given

Linear equations system:  $A \cdot x = B$   $x \geq 0$

Optimal arrangement of work:  $X := \text{Minimize}(D, x)$

$$X^T = \begin{array}{c|cccccccccccccccccccccccccccc} & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 & 17 & 18 & 19 & 20 & 21 & 22 & 23 & 24 & 25 \\ \hline 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \end{array}$$

Optimal plan values of work arrangement, as the matrix 5x5:

Minimal total number of spoilages:  $S := |C \cdot X|$   $S = 39$

$$\begin{pmatrix} X_1 & X_2 & X_3 & X_4 & X_5 \\ X_6 & X_7 & X_8 & X_9 & X_{10} \\ X_{11} & X_{12} & X_{13} & X_{14} & X_{15} \\ X_{16} & X_{17} & X_{18} & X_{19} & X_{20} \\ X_{21} & X_{22} & X_{23} & X_{24} & X_{25} \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 \end{pmatrix}$$

Solution verification:

$$(A \cdot X)^T = (1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1)$$

**Conclusion** On the basis of optimal solution we state that the first job should be done to the first worker, the second to the fifth, the third to the second, the fourth to the fourth and the fifth to the third. Such arrangement of jobs will show the minimum number of spoiled products of 39 pieces.

### 3.2 Arrangement of jobs [AP2a.mcd]

**Example** In production system where are made final wood products, ought to be disposed 5 workers at five working places. While the competition was finished, all assigned conditions satisfied 5 candidates. In order to space workers at working places, there was organized test for their vocational capabilities in view of several criterions [25]. Vocational capability was expressed by summary number of won points, given in T.3.2.

T.3.2

| Workers | Number of points |    |    |    |    |
|---------|------------------|----|----|----|----|
|         | P1               | P2 | P3 | P4 | P5 |
| R1      | 10               | 20 | 8  | 18 | 12 |
| R2      | 20               | 30 | 10 | 15 | 17 |
| R3      | 25               | 20 | 20 | 30 | 16 |
| R4      | 18               | 15 | 15 | 20 | 22 |
| R5      | 10               | 20 | 30 | 30 | 20 |

The assignment is to dispose workers at working places which will provide that total efficiency, expressed through number of points, will be maximal.

#### Solution

Vector of points value:

(ORIGIN := 1)

C :=

|   | 1  | 2  | 3 | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 |
|---|----|----|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1 | 10 | 20 | 8 | 18 | 12 | 20 | 30 | 10 | 15 | 17 | 25 | 20 | 20 | 30 | 16 | 18 | 15 | 15 | 20 | 22 | 10 | 20 | 30 | 30 | 20 |

Criterion function, as function of maximal points:

n := 5

m := 5

$$j := 1..25$$

$$D(x) := \sum_j (C^T)_j \cdot x_j$$

Complete matrix of constraints is formed by opening and filling in blank table. Input table has been got through Component wizard dialoge from Insert – Component menu.

The size of A table:  $(n + m) \cdot n \cdot m = 250$

vector B size:  $m + n = 10$

A :=

|    | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 |
|----|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 2  | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 3  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 1  | 1  | 1  | 1  | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 4  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 1  | 1  | 1  | 1  | 0  | 0  | 0  | 0  | 0  |
| 5  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 1  | 1  | 1  | 1  |
| 6  | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  |
| 7  | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  |
| 8  | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  |
| 9  | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  |
| 10 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  |

The constraints vector that defines the possibility that only one worker can work at only one machine, and that only one job can be given to one worker:

$$B := \begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{pmatrix}$$

Block for solving linear programming model:

Given

Linear equations system:

$$A \cdot x = B$$

$$x \geq 0$$

Optimal works disposition:

$$X := \text{Maximize}(D, x)$$

$$X^T =$$

|   | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 |
|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 | 0 | 0  | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 1  | 0  | 0  |

Maximum value of criterion function is:

$$S := |C \cdot X|$$

$$S = 125$$

The value of optimal arrangement of jobs, arranged as 5x5 matrix:

$$\begin{pmatrix} X_1 & X_2 & X_3 & X_4 & X_5 \\ X_6 & X_7 & X_8 & X_9 & X_{10} \\ X_{11} & X_{12} & X_{13} & X_{14} & X_{15} \\ X_{16} & X_{17} & X_{18} & X_{19} & X_{20} \\ X_{21} & X_{22} & X_{23} & X_{24} & X_{25} \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 \end{pmatrix}$$

Solution verification:

$$(A \cdot X)^T = (1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1)$$

**Conclusion** In view of optimal solution it is stated that the fourth job ought to be given to the first worker, the second one to the second worker, the third to the first, the fourth to the fifth and the fifth to the fourth. Such job disposition will give the greatest value of the criterion function, 125 points.

### 3.3 Job disposition [AP3a\_2.mcd]

**Example** Working organisation ought to open four new working places and for them was advertised vacancy [30]. There were five candidates in narrower selection. Their vocational abilities for doing jobs were tested. The number of won points was given in the table T.3.3.

T.3.3

| <i>Work places</i><br><i>Machines</i> | M1 | M2 | M3 | M4 |
|---------------------------------------|----|----|----|----|
| R1                                    | 5  | 6  | 5  | 1  |
| R2                                    | 4  | 6  | 4  | 1  |
| R3                                    | 8  | 6  | 7  | 6  |
| R4                                    | 2  | 4  | 4  | 4  |
| R5                                    | 6  | 10 | 9  | 4  |

How ought to dispose workers at working places, so that whole efficiency would be maximum?  
Which worker will not be admitted?

#### Solution

Previously defined assignment problem has been opened. After adding one fictitious working place, we get the table T.4.4, and it is condition for forming square matrix 5x5 and apparently closed assignment problem.

## T.3.4

| <i>Work places</i><br><i>Machines</i> | M1 | M2 | M3 | M4 | M5 |
|---------------------------------------|----|----|----|----|----|
| R1                                    | 5  | 6  | 5  | 1  | 0  |
| R2                                    | 4  | 6  | 4  | 1  | 0  |
| R3                                    | 8  | 6  | 7  | 6  | 0  |
| R4                                    | 2  | 4  | 4  | 4  | 0  |
| R5                                    | 6  | 10 | 9  | 4  | 0  |

Vector of points value:

(ORIGIN := 1)

C :=

|   | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 |
|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1 | 5 | 6 | 5 | 1 | 0 | 4 | 6 | 4 | 1 | 0  | 8  | 6  | 7  | 6  | 0  | 2  | 4  | 4  | 4  | 0  | 6  | 10 | 9  | 4  | 0  |

Criterion function, as function of maximal points:

n := 5

m := 5

$$j := 1..n \cdot m$$

$$D(x) := \sum_j (c^T)_j \cdot x_j$$

Complete matrix of constraints is formed by opening and filling in blank table. Input table has been got through Component Wizard dialoge from Insert  Component menu.

Table A size:

$$(n + m) \cdot n \cdot m = 250$$

vector B size:

$$m + n = 10$$

A :=

| 7  | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  |
| 8  | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  |
| 9  | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  |
| 10 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  |

Constraint vector that defines the possibility that only one worker can work at one machine and that only one job can be given to one worker:

$$B := \begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{pmatrix}$$

One initial value (the last):  $x_{25} := 0$

Block for solving linear programming model: Given

System of linear equations:  $A \cdot x = B$   $x \geq 0$

Optimal arrangement of jobs:  $X := \text{Maximize}(D, x)$

$$x^T = \begin{array}{c|cccccccccccccccccccccccccccc} & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 & 17 & 18 & 19 & 20 & 21 & 22 & 23 & 24 & 25 \\ \hline 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \end{array}$$

Values of optimal plan for arrangement of jobs, as 5x5 matrix:

$$Xr := \begin{pmatrix} X_1 & X_2 & X_3 & X_4 & X_5 \\ X_6 & X_7 & X_8 & X_9 & X_{10} \\ X_{11} & X_{12} & X_{13} & X_{14} & X_{15} \\ X_{16} & X_{17} & X_{18} & X_{19} & X_{20} \\ X_{21} & X_{22} & X_{23} & X_{24} & X_{25} \end{pmatrix} \quad Xr = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 \end{pmatrix}$$

The greatest value of criterion function:  $S := |C \cdot X|$   $S = 27$

Solution verification:  $(A \cdot X)^T = (1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1)$

**Conclusion** On the basis of optimal solution, it has been stated that the first working place is necessary to be given to the fifth (fictitious worker, the second to the second worker, the first post to the third worker, the fourth to the fourth one and the third should be given to the fifth worker. The first worker will not be employed.

### 3.4 The open problem of jobs disposition [AP4a\_2.mcd]

**Example** In an engine room of a working organization, it is necessary to perform four tasks. These tasks can be done on six machines. Every machine can work every task, but only one at the same time. With these tasks it is necessary to work four machines, and two to separate for other tasks. The time for processing works on machines/hour/ is given in the table T.3.5.

T.3.5

| <i>Work places</i><br><i>Machines</i> | T1 | T2 | T3 | T4 |
|---------------------------------------|----|----|----|----|
| M1                                    | 9  | 12 | 7  | 12 |
| M2                                    | 14 | 10 | 9  | 11 |
| M3                                    | 8  | 15 | 11 | 15 |
| M4                                    | 12 | 13 | 8  | 14 |
| M5                                    | 10 | 11 | 10 | 10 |
| M6                                    | 11 | 14 | 12 | 9  |

How to dispose tasks on machines so the used time for performing all tasks to be as shorter as possible?

#### Solution

Previously defined assignment problem is open. After adding two fictitious tasks, we get the table T.3.6, and it is the condition for forming square matrix and apparently closed assignment problem.

T.3.6

| <i>Work places</i><br><i>Machines</i> | T1 | T2 | T3 | T4 | T5 | T6 |
|---------------------------------------|----|----|----|----|----|----|
| M1                                    | 9  | 12 | 7  | 12 | 0  | 0  |
| M2                                    | 14 | 10 | 9  | 11 | 0  | 0  |
| M3                                    | 8  | 15 | 11 | 15 | 0  | 0  |
| M4                                    | 12 | 13 | 8  | 14 | 0  | 0  |
| M5                                    | 10 | 11 | 10 | 10 | 0  | 0  |
| M6                                    | 11 | 14 | 12 | 9  | 0  | 0  |

Value vector of points C:

(ORIGIN := 1)

C :=

$$B :=$$

|   |   |
|---|---|
|   | 1 |
| 1 | 1 |
| 2 | 1 |
| 3 | 1 |
| 4 | 1 |
| 5 | 1 |

$$x_{36} := 0$$

Given

$$x \geq 0$$
$$X := \text{Minimize}(D, x)$$

[illegible]

The least value of criterion function is:

$$S := |C \cdot X|$$

$$S = 34$$

Values of optimal jobs disposition, arranged as the matrix 6x6:

$$\begin{pmatrix} X_1 & X_2 & X_3 & X_4 & X_5 & X_6 \\ X_7 & X_8 & X_9 & X_{10} & X_{11} & X_{12} \\ X_{13} & X_{14} & X_{15} & X_{16} & X_{17} & X_{18} \\ X_{19} & X_{20} & X_{21} & X_{22} & X_{23} & X_{24} \\ X_{25} & X_{26} & X_{27} & X_{28} & X_{29} & X_{30} \\ X_{31} & X_{32} & X_{33} & X_{34} & X_{35} & X_{36} \end{pmatrix} = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 \end{pmatrix}$$

Solution verification:

$$(A \cdot X)^T = (1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1)$$

**Conclusion** the first job we should process at the third machine, the second one at the second machine, the third at the first and the fourth on the sixth. The machines M4 and M5 will not be used for performing these jobs. The variables  $X_{23}$  and  $X_{30}$  are supplementary variables and they there point which machines will not be used. Minimal time possible for performing these jobs is 34 hours.

### 3.5 Disposition of students [AP5a\_2.mcd]

**Example** At sitting for an examination was given eight question groups, and the exam take six students, after getting one group of questions. Students' level of knowledge for single groups of question is given with the next marks, students can get.

T.3.7

| Question \ Student | Q1 | Q2 | Q3 | Q4 | Q5 | Q6 | Q7 | Q8 |
|--------------------|----|----|----|----|----|----|----|----|
| S1                 | 6  | 8  | 9  | 5  | 7  | 10 | 6  | 5  |
| S2                 | 7  | 10 | 8  | 9  | 8  | 5  | 6  | 7  |
| S3                 | 6  | 6  | 5  | 5  | 9  | 9  | 10 | 10 |
| S4                 | 10 | 9  | 7  | 7  | 6  | 6  | 6  | 5  |
| S5                 | 9  | 8  | 5  | 6  | 6  | 7  | 7  | 8  |
| S6                 | 8  | 9  | 10 | 10 | 9  | 9  | 8  | 7  |

If each student should answer only one group of questions, determine the best possible one (with the highest average mark) and the possible worst (with the lowest average mark) success.

### Solution

Previously defined assignment problem is opened. After adding two fictitious students, we get the table T.3.8, which is condition for forming square matrix and temporarily closed assignment problem.

T.3.8

| <i>Question</i><br><i>Student</i> | Q1 | Q2 | Q3 | Q4 | Q5 | Q6 | Q7 | Q8 |
|-----------------------------------|----|----|----|----|----|----|----|----|
| S1                                | 6  | 8  | 9  | 5  | 7  | 10 | 6  | 5  |
| S2                                | 7  | 10 | 8  | 9  | 8  | 5  | 6  | 7  |
| S3                                | 6  | 6  | 5  | 5  | 9  | 9  | 10 | 10 |
| S4                                | 10 | 9  | 7  | 7  | 6  | 6  | 6  | 5  |
| S5                                | 9  | 8  | 5  | 6  | 6  | 7  | 7  | 8  |
| S6                                | 8  | 9  | 10 | 10 | 9  | 9  | 8  | 7  |
| S7                                | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| S8                                | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

Previously defined assignment problem is closed, where is noticeable square matrix 8x8.

Value vector of the point C:

(ORIGIN := 1)

C :=

|   |   |   |   |   |   |    |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---|---|---|---|---|---|----|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|   | 1 | 2 | 3 | 4 | 5 | 6  | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 |
| 1 | 6 | 8 | 9 | 5 | 7 | 10 | 6 | 5 | 7 | 10 | 8  | 9  | 8  | 5  | 6  | 7  | 6  | 6  | 5  | 5  | 9  | 9  | 10 |

Criterion function as the function of maximal points:

n := 8

m := 8

$$j := 1 \dots n \cdot m \qquad D(x) := \sum_j (c^T)_j \cdot x_j$$

The complete matrix of limits coefficients is being formed by opening and filling in blank table. We get Input Table through the dialogue Component Wizard from the menu Insert ○ Component.

Table A value:  $(n + m) \cdot n \cdot m = 1024$

vector B value:  $m + n = 16$

[illegible]

B :=

|   |   |  |
|---|---|--|
|   | 1 |  |
| 1 | 1 |  |
| 2 | 1 |  |
| 3 | 1 |  |
| 4 | 1 |  |

$$x_{64} := 0$$

Given

$$x \geq 0$$
$$X := \text{Maximize}(D, x)$$
[illegible]
$$S = 58$$

$$Xr := \begin{pmatrix} X_1 & X_2 & X_3 & X_4 & X_5 & X_6 & X_7 & X_8 \\ X_9 & X_{10} & X_{11} & X_{12} & X_{13} & X_{14} & X_{15} & X_{16} \\ X_{17} & X_{18} & X_{19} & X_{20} & X_{21} & X_{22} & X_{23} & X_{24} \\ X_{25} & X_{26} & X_{27} & X_{28} & X_{29} & X_{30} & X_{31} & X_{32} \\ X_{33} & X_{34} & X_{35} & X_{36} & X_{37} & X_{38} & X_{39} & X_{40} \\ X_{41} & X_{42} & X_{43} & X_{44} & X_{45} & X_{46} & X_{47} & X_{48} \\ X_{49} & X_{50} & X_{51} & X_{52} & X_{53} & X_{54} & X_{55} & X_{56} \\ X_{57} & X_{58} & X_{59} & X_{60} & X_{61} & X_{62} & X_{63} & X_{64} \end{pmatrix} \quad Xr = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \end{pmatrix}$$

Solution verification:  $(A \cdot X)^T = (1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1)$

In view of optimal solution the next results are concluded concerning maximum, when there are being combined group of questions and the next structure students:

T.3.9

| Student           | S1 | S2 | S3 | S4 | S5 | S6 |
|-------------------|----|----|----|----|----|----|
| Group of question | Q6 | Q2 | Q7 | Q1 | Q8 | Q4 |
| Mark              | 10 | 10 | 10 | 10 | 8  | 10 |

The highest average mark is:  $\frac{S}{m-2} = 9.667$

One initial value (last):  $x_{64} := 0$

Block for solving linear programming models: Given

Linear equations system:  $A \cdot x = B \quad x \geq 0$

Optimal disposition of jobs:  $X := \text{Minimize}(D, x)$

$$X^T = \begin{array}{c|cccccccccccccccccccccccccccc} & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 & 17 & 18 & 19 & 20 & 21 & 22 & 23 & 24 \\ \hline 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \end{array}$$

The values of optimal plan for jobs disposition, as the matrix 8x8:

The least value of criterion function:  $S := |C \cdot X| \quad S = 34$

$$X_r := \begin{pmatrix} X_1 & X_2 & X_3 & X_4 & X_5 & X_6 & X_7 & X_8 \\ X_9 & X_{10} & X_{11} & X_{12} & X_{13} & X_{14} & X_{15} & X_{16} \\ X_{17} & X_{18} & X_{19} & X_{20} & X_{21} & X_{22} & X_{23} & X_{24} \\ X_{25} & X_{26} & X_{27} & X_{28} & X_{29} & X_{30} & X_{31} & X_{32} \\ X_{33} & X_{34} & X_{35} & X_{36} & X_{37} & X_{38} & X_{39} & X_{40} \\ X_{41} & X_{42} & X_{43} & X_{44} & X_{45} & X_{46} & X_{47} & X_{48} \\ X_{49} & X_{50} & X_{51} & X_{52} & X_{53} & X_{54} & X_{55} & X_{56} \\ X_{57} & X_{58} & X_{59} & X_{60} & X_{61} & X_{62} & X_{63} & X_{64} \end{pmatrix} \quad X_r = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}$$

Solution verification:  $(A \cdot X)^T = (1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1)$

On the basis of optimal solution, there are stated the next results referred to minimum, when one combines group of questions and the students of the next structure:

T.3.10

| <i>Student</i>           | S1 | S2 | S3 | S4 | S5 | S6 |
|--------------------------|----|----|----|----|----|----|
| <i>Group of question</i> | Q8 | Q6 | Q4 | Q7 | Q3 | Q1 |
| <i>Mark</i>              | 5  | 5  | 5  | 6  | 5  | 8  |

The least average mark is:  $\frac{S}{m-2} = 5.667$

## 4. NONLINEAR PROGRAMMING

### 4.1 A model of nonlinear programming [NP1.mcd]

**Example** Solve a task of non-linear programming on the basis of the model with three variables and charges function (criterion), through method with of finding unconditional extreme of charges function  $T(x_1, x_2, x_3)$ . Define stationary points (vectors) of optimum and define their nature.

$$T(x_1, x_2, x_3) := 4 \cdot x_1^2 + \frac{1}{12} \cdot x_2^3 + 7 \cdot x_3^2 - x_2 - 2 \cdot x_1 + \frac{7}{2} \cdot x_3 + 7$$

#### Solution

Necessary conditions for determining stationary points are being found in view of partial derivations for variables:  $x_1, x_2$  i  $x_3$ .

$$\frac{\partial}{\partial x_1} T(x_1, x_2, x_3) \rightarrow 8 \cdot x_1 - 2$$

$$\frac{\partial}{\partial x_2} T(x_1, x_2, x_3) \rightarrow \frac{1}{4} \cdot x_2^2 - 1$$

$$\frac{\partial}{\partial x_3} T(x_1, x_2, x_3) \rightarrow 14 \cdot x_3 + \frac{7}{2}$$

For determining stationary vectors  $x^{<1>}$  and  $x^{<2>}$  previously found derivations are equaled with zero:

ORIGIN := 1

Given

$$8 \cdot x_1 - 2 = 0$$

$$\frac{1}{4} \cdot x_2^2 - 1 = 0$$

$$14 \cdot x_3 + \frac{7}{2} = 0$$

$$\text{MinErr}(x_1, x_2, x_3) \rightarrow \begin{pmatrix} \frac{1}{4} & \frac{1}{4} \\ 2 & -2 \\ -\frac{1}{4} & -\frac{1}{4} \end{pmatrix} \quad \text{what can be presented by the matrix:} \quad x := \begin{pmatrix} \frac{1}{4} & \frac{1}{4} \\ 2 & -2 \\ -\frac{1}{4} & -\frac{1}{4} \end{pmatrix}$$

In view of previous results, we find that there are two stationary function points, presented through vectors:

$$x^{<1>} = \begin{pmatrix} 0.25 \\ 2 \\ -0.25 \end{pmatrix} \quad x^{<2>} = \begin{pmatrix} 0.25 \\ -2 \\ -0.25 \end{pmatrix} \quad \begin{matrix} x_{1,1} = 0.25 & x_{1,2} = 0.25 \\ x_{2,1} = 2 & x_{2,2} = -2 \\ x_{3,1} = -0.25 & x_{3,2} = -0.25 \end{matrix}$$

By derivation of higher progression and mixed derivations of many variables, are being stated its characteristics in environment of stationary points. These derivations can be directly arranged in determinants for stationary points:

$$\det1(x_1, x_2, x_3) := \left| \frac{\partial^2}{\partial x_1^2} T(x_1, x_2, x_3) \right| \rightarrow 8$$

$$\det2(x_1, x_2, x_3) := \left| \begin{pmatrix} \frac{\partial^2}{\partial x_1^2} T(x_1, x_2, x_3) & \frac{\partial}{\partial x_1} \frac{\partial}{\partial x_2} T(x_1, x_2, x_3) \\ \frac{\partial}{\partial x_2} \frac{\partial}{\partial x_1} T(x_1, x_2, x_3) & \frac{\partial^2}{\partial x_2^2} T(x_1, x_2, x_3) \end{pmatrix} \right| \rightarrow 4 \cdot x_2$$

$$\det3(x_1, x_2, x_3) := \left| \begin{pmatrix} \frac{\partial^2}{\partial x_1^2} T(x_1, x_2, x_3) & \frac{\partial}{\partial x_1} \frac{\partial}{\partial x_2} T(x_1, x_2, x_3) & \frac{\partial}{\partial x_1} \frac{\partial}{\partial x_3} T(x_1, x_2, x_3) \\ \frac{\partial}{\partial x_2} \frac{\partial}{\partial x_1} T(x_1, x_2, x_3) & \frac{\partial^2}{\partial x_2^2} T(x_1, x_2, x_3) & \frac{\partial}{\partial x_2} \frac{\partial}{\partial x_3} T(x_1, x_2, x_3) \\ \frac{\partial}{\partial x_3} \frac{\partial}{\partial x_1} T(x_1, x_2, x_3) & \frac{\partial}{\partial x_3} \frac{\partial}{\partial x_2} T(x_1, x_2, x_3) & \frac{\partial^2}{\partial x_3^2} T(x_1, x_2, x_3) \end{pmatrix} \right| \rightarrow 56 \cdot x_2$$

Concrete values of determinants for stationary points, can be stated through substitution of values for numerical elements of the first vector, then the second one. In view of that follow the results:

$$\begin{pmatrix} \det1(x_{1,1}, x_{2,1}, x_{3,1}) \\ \det2(x_{1,1}, x_{2,1}, x_{3,1}) \\ \det3(x_{1,1}, x_{2,1}, x_{3,1}) \end{pmatrix} \rightarrow \begin{pmatrix} 8 \\ 8 \\ 112 \end{pmatrix} \quad \begin{pmatrix} \det1(x_{1,2}, x_{2,2}, x_{3,2}) \\ \det2(x_{1,2}, x_{2,2}, x_{3,2}) \\ \det3(x_{1,2}, x_{2,2}, x_{3,2}) \end{pmatrix} \rightarrow \begin{pmatrix} 8 \\ -8 \\ -112 \end{pmatrix}$$

As all values are determinants ( $\det1, \det2$  i  $\det3$ )  $> 0$ , for  $x^{<1>}$  here results that the function  $T(x_{1,1}, x_{2,1}, x_{3,1})$  has local minimum with numerical value:

$$T(x_{1,1}, x_{2,1}, x_{3,1}) = 4.979$$

Through similar procedure, by substitution of the vector  $x^{<2>}$ , we are testing the amount of criterion changes function, in this stationary point:

$$T(x_{1,2}, x_{2,2}, x_{3,2}) = 7.646$$

As:  $T(x_{1,2}, x_{2,2}, x_{3,2}) > T(x_{1,1}, x_{2,1}, x_{3,1}) = 1$  the solution is verified, so it comes that the first point  $T(x_{1,1}, x_{2,1}, x_{3,1})$  is global minimum of charges function.

## 4.2 Profit maximization through nonlinear programming method [NP2.mcd]

**Example** On the basis of defined functions  $R(q)$  – incomes and  $T(q)$  – costs [2]:

- Define optimal volume of sale for profit maximization.
- State value of profit for minimal average costs.
- Check and design on a chart functions of income, costs and profit.
- How great is interval of great power?

### Solution

Function of income:  $R(q) := 400 \cdot q - q^2$

Function of costs:  $T(q) := 3 \cdot q^2 + 1200$

Profit is defined as difference of total incomes and total costs:

$$\Pi(q) := R(q) - T(q) \rightarrow 400 \cdot q - 4 \cdot q^2 - 1200$$

The conditions achieving maximum of profit function are that the first derivation should be zero and the second one negative:

$$\frac{d}{dq} \Pi(q) \rightarrow 400 - 8 \cdot q \qquad \frac{d^2}{dq^2} \Pi(q) \rightarrow -8$$

Consequently, profit maximum is achieved when the volume of production (sale) is 50, so then is realized the profit of 8800 /nj/.

$$\frac{d}{dq} \Pi(q) = 0 \text{ solve, } q \rightarrow 50 \qquad \Pi(50) = 8800$$

Minimal average costs can present criterion for production optimization. In the concrete case they are achieved through the next procedures:

$$t(q) := \frac{T(q)}{q} \qquad t(q) \rightarrow \frac{(3 \cdot q^2 + 1200)}{q} \qquad \frac{d^2}{dq^2} t(q) \text{ simplify } \rightarrow \frac{2400}{q^3}$$

$$\frac{d}{dq} t(q) = 0 \text{ solve, } q \rightarrow \begin{pmatrix} 20 \\ -20 \end{pmatrix} \qquad \Pi(20) = 5200$$

For volume of sale (production) of  $q=20$  product units, we can realize minimal average costs, and the profit then realized is 5200 /nj/.

**Fig. 4.1** The chart of functions for profit, costs and income

#### $\pi$ Points of section for the functions $R(q)$ and $T(q)$

Initial value of solution:  $q := 50$

Solution of functions cross-section:  $Q1 := \text{root}(R(q) - T(q), q)$   $Q1 = 96.9$

Verification of functions values: 
$$\begin{pmatrix} R(Q1) \\ T(Q1) \end{pmatrix} = \begin{pmatrix} 29371.247 \\ 29371.247 \end{pmatrix}$$

One should note that the first coordinates of these points are exactly also the first coordinates of zero value of profit function.

#### Points of selection for the functions $R(q)$ and $P(q)$

Solution of functions cross-selection:  $Q2 := \text{root}(R(q) - \Pi(q), q)$   $Q2 = -20i$

Verification of functions values: 
$$\begin{pmatrix} R(Q2) \\ \Pi(Q2) \end{pmatrix} = \begin{pmatrix} 400 - 8000i \\ 400 - 8000i \end{pmatrix}$$

In relation of the two functions  $R(q)$  and  $P(q)$  we can not find real solution of cross-selection, but only complex (imaginary). Consequently, it follows that it is impossible that profit should be equal to incomes.

### $\pi$ Points of section for the functions $T(q)$ and $P(q)$

Solution of functions cross-selection:  $Q3 := \text{root}(T(q) - \Pi(q), q)$   $Q3 = 50.33$

Verification of functions value:  $\begin{pmatrix} \Pi(Q3) \\ T(Q3) \end{pmatrix} = \begin{pmatrix} 8799.562 \\ 8799.562 \end{pmatrix}$

Interval of earning power is the interval for which profit is positive, or alternative field where incomes are greater than costs:

$$\begin{aligned} \Pi(Q) &:= 400 \cdot Q - 4 \cdot Q^2 - 1200 & A &:= \Pi(Q) \text{ coeffs}, Q \rightarrow \begin{pmatrix} -1200 \\ 400 \\ -4 \end{pmatrix} \\ q &:= \text{polyroots}(A) & q &= \begin{pmatrix} 3.096 \\ 96.904 \end{pmatrix} & q_0 &= 3.096 & q_1 &= 96.904 \end{aligned}$$

In concrete example it is the interval  $[q_0, q_1]$ . In that interval company realizes its gaining business (operations). Consequently, it is exactly the field between two zeros of profit function, respectively the field between two points of section of total income function and total costs.

## 4.3 Conditions of production optimality (optimum) [NP3.mcd]

**Example** For the product  $x$  are given demand function  $x(p)$  and costs function  $C(x)$ . Determine production for which is being realized maximal profit and its amount.

Starting data:  $a := -\frac{1}{4}$   $b := 1200$   $c := 2$   $d := 900$

Demand function:  $x(p) := a \cdot p + b$

Costs function:  $C(x) := c \cdot x^2 + d$

Inverse form of demand function:  $p(x) := a \cdot p + b - x = 0 \text{ solve } p \rightarrow 4800 - 4 \cdot x$

Or by redefinition (only change of marks,  $x \rightarrow X$ ):  $p(X) \rightarrow 4800 - 4 \cdot X$

In come function is then:  $P(X) := X \cdot p(X) \rightarrow X \cdot (4800 - 4 \cdot X)$

Redefinition of costs function:  $C(X) \rightarrow 2 \cdot X^2 + 900$

Then profit function is defined as:

$$D(x) := P(x) - C(x) \text{ simplify } \rightarrow 4800 \cdot x - 6 \cdot x^2 - 900$$

Izvodna funkcija dobiti je:

$$D'(x) := \frac{d}{dx} D(x) \rightarrow 4800 - 12 \cdot x$$

Solving derived equation, we get a solution  $x_0$  as optimal value of production:

$$\text{Given} \quad D'(x) = 0 \quad x_0 := \text{Find}(x) \rightarrow 400$$

So, maximal profits:

$$D(x_0) \rightarrow 959100$$

The interval of earning power is determined from the conditions:

$$\text{Given} \quad D(x) = 0$$

Solving square equation we get solution vector:

$$x := \text{Find}(x) \rightarrow (400 + 5 \cdot \sqrt{6394} \quad 400 - 5 \cdot \sqrt{6394}) \quad x^T = \begin{pmatrix} 799.812 \\ 0.188 \end{pmatrix} \quad x_r := x^T$$

The earning power is between the values:

$$x_{r_0} = 799.812 \quad \text{i} \quad x_{r_1} = 0.188$$

#### 4.4 Utility function-optimal volume of purchase of goods [NP4.mcd]

**Example** For the given utility function  $U$  and budget equation  $D$  with fixed budget  $Do$  determine optimal purchase volume (acquisition) of observed goods, so to realize maximal utility [23].

Starting parameters:

$$p_1 := 45$$

$$p_2 := 24$$

Values of fixed budget  $Do$ :

$$Do := 680$$

Utility function:

$$U(x, y) := 85 \cdot x \cdot y^2$$

Lagrange's equation:

$$G(x, y, \lambda) := U(x, y) + \lambda \cdot (Do - D(x, y))$$

Partial deviations for  $x$ ,  $y$  and  $\lambda$ :

$$G1(x, y, \lambda) := \frac{\partial}{\partial x} G(x, y, \lambda)$$

$$G1(x, y, \lambda) \rightarrow 85 \cdot y^2 - 45 \cdot \lambda$$

$$G2(x, y, \lambda) := \frac{\partial}{\partial y} G(x, y, \lambda)$$

$$G2(x, y, \lambda) \rightarrow 170 \cdot x \cdot y - 24 \cdot \lambda$$

$$G3(x, y, \lambda) := \frac{\partial}{\partial \lambda} G(x, y, \lambda)$$

$$G3(x, y, \lambda) \rightarrow 680 - 45 \cdot x - 24 \cdot y$$

Other partial derivations are:

$$F11(x, y, \lambda) := \frac{\partial^2}{\partial x^2} G(x, y, \lambda)$$

$$F11(x, y, \lambda) \rightarrow 0$$

$$F12(x, y, \lambda) := \frac{\partial}{\partial x} \frac{\partial}{\partial y} G(x, y, \lambda)$$

$$F12(x, y, \lambda) \rightarrow 170 \cdot y$$

$$F21(x, y, \lambda) := \frac{\partial}{\partial y} \frac{\partial}{\partial x} G(x, y, \lambda)$$

$$F21(x, y, \lambda) \rightarrow 170 \cdot y$$

$$F22(x, y, \lambda) := \frac{\partial^2}{\partial y^2} G(x, y, \lambda)$$

$$F22(x, y, \lambda) \rightarrow 170 \cdot x$$

Determining optimal value of goods purchase. For initial values is formed block for calculation:

$$x := 2 \quad y := 2 \quad \lambda := 1$$

Given

$$G1(x, y, \lambda) = 0$$

$$G2(x, y, \lambda) = 0$$

$$G3(x, y, \lambda) = 0$$

Optimal values of the two variables ( $x_0$ ,  $y_0$ ) make:

$$\begin{pmatrix} x_0 \\ y_0 \\ \lambda_0 \end{pmatrix} := \text{Find}(x, y, \lambda)$$

$$\begin{pmatrix} x_0 \\ y_0 \end{pmatrix} = \begin{pmatrix} 5.037 \\ 18.889 \end{pmatrix}$$

With this maximal value of utility function is:

$$U(x_0, y_0) = 152759.031$$

Values of partial derivations for optimal values:

$$F11(x_0, y_0, \lambda) = 0$$

$$F12(x_0, y_0, \lambda) = 3211.111$$

$$F21(x_0, y_0, \lambda) = 3211.111$$

$$F22(x_0, y_0, \lambda) = 856.296$$

The condition that verifies maximal values of utility function is expressed by positive value of Hessian determinant.

$$H := \begin{pmatrix} F_{11}(x_0, y_0, \lambda) & F_{12}(x_0, y_0, \lambda) & -p_1 \\ F_{21}(x_0, y_0, \lambda) & F_{22}(x_0, y_0, \lambda) & -p_2 \\ -p_1 & -p_2 & 0 \end{pmatrix}$$

$$H = 5202000$$

$$H > 0 = 1 \quad (\text{affirmatively})$$

From where is confirmed that Hessian determinant is positive.

#### 4.5 Optimization of enzyme product [NP5.mcd]

**Example** Optimization of models for biological processes can be observed from many views. First, that during evolution has happened significant bio-chemical changes. Now researchers should determine different metabolic pathways and genetic models caused by them. The second is the method of artificial improvement of these systems, because of different demands as insulin production out of DNA resources, before it is isolated from animal glands and the like. Taking this in consideration, researchers have developed mathematical program for ethyl-alcohol optimization, glycerin (e) (propan-triol) and production of carbohydrates in *Saccharomyces cerevisiae* in conditions of broken of cell culture in pH 4.5.

Starting parameters connected with chemical compounds, are given in the next table:

T.4.1

| <i>Chemical compound</i>  | <i>Concentration</i> | <i>Concentration</i>                     | <i>Concentration</i> |
|---------------------------|----------------------|--|----------------------|
| Internal glucose          | $x_1 := 0.034$       | Phosphofructokinase                      | $x_8 := 31.7$        |
| Glucose-6-phosphate       | $x_2 := 1.01$        | Glyceraldehyde-3-phosphate dehydrogenase | $x_9 := 49.9$        |
| Fructose-1,6-diphosphate  | $x_3 := 9.144$       | Pyruvate kinase                          | $x_{10} := 3440$     |
| Phosphoenolpyruvate       | $x_4 := 0.0095$      | Polysaccharide production                | $x_{11} := 14.31$    |
| Adenozin-tri-fosfat (ATP) | $x_5 := 1.1278$      | Glycerol production:                     | $x_{12} := 203$      |
| Glucose uptake            | $x_6 := 19.7$        | ATPase                                   | $x_{13} := 25.1$     |
| Enzim hexokinase          | $x_7 := 68.5$        | NAD/NADH ratio                           | $x_{14} := 0.042$    |

#### Solution

Exact model with limit functions:

Given

Sugar transport: 
$$x1 = 0.8122 \cdot x2^{-0.2344} \cdot x6 - 2.8632 \cdot x1^{0.7464} \cdot x5^{0.0243} \cdot x7$$

Hexokinase enzyme:

$$x2 = 2.8632 \cdot x1 \cdot x5^{0.0243} \cdot x7 - 0.5236 \cdot x2^{0.735} \cdot x5^{-0.394} \cdot x8^{0.999} \cdot x11^{0.001}$$

The kind of enzyme whose reaction causes compound breakdown (Phosphofructokinase reaction).

$$x3 = 0.5232 \cdot x2^{0.7318} \cdot x5^{-0.3941} \cdot x8$$

Enzim Pyruvatekinase:

$$x4 = 0.022 \cdot x3^{0.6159} \cdot x5^{0.1308} \cdot x9 \cdot x14^{-0.6088} - 0.0945 \cdot x3^{0.05} \cdot x4^{0.533} \cdot x5^{-0.0822} \cdot x10$$

ATP (Adenozin-tri- phosphate):

$$x5 = - \left( 3.2097 \cdot x1^{0.198} \cdot x2^{0.196} \cdot x5^{0.372} \cdot x7^{0.265} \cdot x8^{0.265} \cdot x11^{0.002} \cdot x13^{0.47} \right) \dots \\ + 0.0913 \cdot x3^{0.333} \cdot x4^{0.266} \cdot x5^{0.024} \cdot x9^{0.5} \cdot x10^{0.5} \cdot x14^{-0.304}$$

Finding variables for constant state of concentration:

$$K := \text{Find}(x1, x2, x3, x4, x5, x6, x7, x8, x9, x10, x11, x12, x13, x14)$$

Solution of equations system:

$$K^T = (0.04 \ 0.8 \ 8.45 \ 0.01 \ 1.24 \ 24.47 \ 80.46 \ 20.76 \ 50.24 \ 3367.16 \ 14.31 \ 203 \ 24.97 \ 0.04)$$

The hypothesis is that optimization of ethyl-alcohol production a real function and it is necessary to invent such a value, that the flowing through would be maximal one.

$$C(x1, x2, x3, x4, x5, x6, x7, x8, x9, x10, x11, x12, x13, x14) := 0.0945 \cdot x3^{0.05} \cdot x4^{0.533} \cdot x5^{-0.0822} \cdot x10$$

The values of chemical compounds will be here initial for (non) equations of a constant state. According to Clifford (?) we can decide how much is to each enzyme allowed to change itself (with supposition that it can be physiologically and bio-technically realized). In terms of it are set limits to metabolite concentration:

Limit functions:

Given

$$\begin{array}{llll}
0.03 \leq x_1 \leq 0.04 & 1.1 \leq x_5 \leq 1.15 & 40 \leq x_9 \leq 55 & 20 \leq x_{13} \leq 30 \\
0.96 \leq x_2 \leq 1.1 & 16 \leq x_6 \leq 21 & 3200 \leq x_{10} \leq 10000 & x_{14} \leq 0.05 \\
8.9 \leq x_3 \leq 9.4 & 60 \leq x_7 \leq 72 & x_{11} \leq 15 & \\
0.07 \leq x_4 \leq 0.11 & 28 \leq x_8 \leq 35 & x_{12} \leq 210 & 
\end{array}$$

Maximization of criterion function (of flow), with optimal values of arguments.

$$Z := \text{Maximize}(C, x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8, x_9, x_{10}, x_{11}, x_{12}, x_{13}, x_{14})$$

$$Z^T = (0.034 \ 1.1 \ 9.4 \ 0.11 \ 1.1 \ 21 \ 68.571 \ 30.464 \ 55 \ 10000 \ 3.578 \ 101.5 \ 27.853 \ 0.021)$$

## 5. DYNAMIC PROGRAMMING

### 5.1 One-dimensional process of optimal resources distribution [DP1.mcd]

**Example** inside a company is necessary to distribute a homogenous resource to the amount of  $S=8$  units [19]. The resource is distributed to three plants so that separate values are integer and not greater than 5. The realized profit in single plants in linear way depends on the quantity of the distributed resource. Profit for resource unit is: for the first plant  $c_1=4/nj/$ , the second plant:  $c_2=5/nj/$ , the third plant:  $c_3=2/nj/$ . The resource needs to be distributed so that we get maximal profit for the company on the whole. It is necessary:

- to form mathematical model of problem, and
- to determine optimal plan of resources distribution applying the method of dynamic programming

Starting data: Unit profits:  $c_1 := 4$   $c_2 := 5$   $c_3 := 2$

a) Mathematical model of problem makes function of aim:  $F(x) := c_1 \cdot x_1 + c_2 \cdot x_2 + c_3 \cdot x_3$

The conditions concerning limit (action) are:

$$x_1 + x_2 + x_3 \leq S \quad 0 \leq x_1 \leq 5 \quad 0 \leq x_2 \leq 5 \quad 0 \leq x_3 \leq 5$$

Marks of resource quantity:

$$x3_0 := 0 \quad x3_1 := 1 \quad x3_2 := 2 \quad x3_3 := 3 \quad x3_4 := 4 \quad x3_5 := 5$$

Recurrent relation of direct profit from the distribution for the first resource:

$$S := 0..8 \quad f1_S := \text{if}(c1 \cdot S > c1 \cdot x3_5, c1 \cdot x3_5, c1 \cdot S) \quad f1_S = \quad \max(f1) = 20$$

$$S := 8 \quad x_2 := 0..S - 3 \quad f_{28}_{x_2} := c_2 \cdot x_2 + f_{1_{S-x_2}} \quad f_{28}_{x_2} = \max(f_{28}) = 37$$

|    |
|----|
| 20 |
| 25 |
| 30 |
| 35 |
| 36 |
| 37 |

Vector relation of the distribution for the third resource:

$$f30 := c3 \cdot x3_0 + \max(f20)$$

$$f30 = 0$$

$$\max(f30) = 0$$

$$f31 := \begin{pmatrix} c3 \cdot x3_0 + \max(f21) \\ c3 \cdot x3_1 + \max(f20) \end{pmatrix} \rightarrow \begin{pmatrix} 5 \\ 2 \end{pmatrix}$$

$$f32 := \begin{pmatrix} c3 \cdot x3_0 + \max(f22) \\ c3 \cdot x3_1 + \max(f21) \\ c3 \cdot x3_2 + \max(f20) \end{pmatrix} \rightarrow \begin{pmatrix} 10 \\ 7 \\ 4 \end{pmatrix}$$

$$\max(f31) = 5$$

$$\max(f32) = 10$$

$$f33 := \begin{pmatrix} c3 \cdot x3_0 + \max(f23) \\ c3 \cdot x3_1 + \max(f22) \\ c3 \cdot x3_2 + \max(f21) \\ c3 \cdot x3_3 + \max(f20) \end{pmatrix} \rightarrow \begin{pmatrix} 15 \\ 12 \\ 9 \\ 6 \end{pmatrix}$$

$$f34 := \begin{pmatrix} c3 \cdot x3_0 + \max(f24) \\ c3 \cdot x3_1 + \max(f23) \\ c3 \cdot x3_2 + \max(f22) \\ c3 \cdot x3_3 + \max(f21) \\ c3 \cdot x3_4 + \max(f20) \end{pmatrix} \rightarrow \begin{pmatrix} 20 \\ 17 \\ 14 \\ 11 \\ 8 \end{pmatrix}$$

$$\max(f33) = 15$$

$$\max(f34) = 20$$

$$f35 := \begin{pmatrix} c3 \cdot x3_0 + \max(f25) \\ c3 \cdot x3_1 + \max(f24) \\ c3 \cdot x3_2 + \max(f23) \\ c3 \cdot x3_3 + \max(f22) \\ c3 \cdot x3_4 + \max(f21) \\ c3 \cdot x3_5 + \max(f20) \end{pmatrix} \rightarrow \begin{pmatrix} 25 \\ 22 \\ 19 \\ 16 \\ 13 \\ 10 \end{pmatrix}$$

$$f36 := \begin{pmatrix} c3 \cdot x3_0 + \max(f26) \\ c3 \cdot x3_1 + \max(f25) \\ c3 \cdot x3_2 + \max(f24) \\ c3 \cdot x3_3 + \max(f23) \\ c3 \cdot x3_4 + \max(f22) \\ c3 \cdot x3_5 + \max(f21) \end{pmatrix} \rightarrow \begin{pmatrix} 29 \\ 27 \\ 24 \\ 21 \\ 18 \\ 15 \end{pmatrix}$$

$$\max(f35) = 25$$

$$\max(f36) = 29$$

$$f37 := \begin{pmatrix} c3 \cdot x3_0 + \max(f27) \\ c3 \cdot x3_1 + \max(f26) \\ c3 \cdot x3_2 + \max(f25) \\ c3 \cdot x3_3 + \max(f24) \\ c3 \cdot x3_4 + \max(f23) \\ c3 \cdot x3_5 + \max(f22) \end{pmatrix} \rightarrow \begin{pmatrix} 33 \\ 31 \\ 29 \\ 26 \\ 23 \\ 20 \end{pmatrix}$$

$$f38 := \begin{pmatrix} c3 \cdot x3_0 + \max(f28) \\ c3 \cdot x3_1 + \max(f27) \\ c3 \cdot x3_2 + \max(f26) \\ c3 \cdot x3_3 + \max(f25) \\ c3 \cdot x3_4 + \max(f24) \\ c3 \cdot x3_5 + \max(f23) \end{pmatrix} \rightarrow \begin{pmatrix} 37 \\ 35 \\ 33 \\ 31 \\ 28 \\ 25 \end{pmatrix}$$

$$\max(f37) = 33$$

$$\max(f38) = 37$$

Direct profits of distribution in function of available resource and number of lines:  $S := 0..8$

$$\begin{array}{ccccc}
 f1_S = 20 & \begin{pmatrix} 0 \\ 4 \\ 8 \\ 12 \\ 16 \\ 20 \\ 20 \\ 20 \\ 20 \end{pmatrix} & f2_S := & \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} & f3_S := & \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} \\
 & f1 = & \begin{array}{|c|} \hline \max(f20) \\ \hline \max(f21) \\ \hline \max(f22) \\ \hline \max(f23) \\ \hline \max(f24) \\ \hline \max(f25) \\ \hline \max(f26) \\ \hline \max(f27) \\ \hline \max(f28) \\ \hline \end{array} & f2 = & \begin{array}{|c|} \hline \max(f30) \\ \hline \max(f31) \\ \hline \max(f32) \\ \hline \max(f33) \\ \hline \max(f34) \\ \hline \max(f35) \\ \hline \max(f36) \\ \hline \max(f37) \\ \hline \max(f38) \\ \hline \end{array} & f3 =
 \end{array}$$

The greatest profit is /nj/:  $F(x) := 37$

Optimal resource quantities:  $x_1 := 3$   $x_2 := 5$   $x_3 := 0$

The solution may be expressed as well as:  $\text{ORIGIN} := 2$   $x = \begin{pmatrix} 0 \\ 3 \\ 5 \\ 0 \end{pmatrix}$   $F(x) = 37$

## 6. MULTICRITERIA OPTIMIZATION

### 6.1 The method of simple additive weights [MO1.mcd]

**Example** Choose the most acceptable variant through the method of simple additive weights provided that all [8]:

- Criteria are of the same significance (T1),
- Of different significance (T2).

#### Solution

- Weight coefficients of criterion are of the same significance.

Linearized matrix of decision is defined as:

$$Q := \begin{pmatrix} 0.5 & 0.5 & 1 & 0.3333 & 0.5556 \\ 0.3333 & 1 & 0.6 & 1 & 0.3333 \\ 0.6667 & 0.3333 & 0.4 & 0.6667 & 0.7778 \\ 1 & 0.2 & 0.4 & 0.6667 & 1 \end{pmatrix}$$

The vector of weight coefficients is given as:

$$T1 := (0.2 \ 0.2 \ 0.2 \ 0.2 \ 0.2)$$

Applying maximization criterion it follows that:

$$R := \begin{bmatrix} |T1 \cdot (Q^T)^{\langle 0 \rangle}| \\ |T1 \cdot (Q^T)^{\langle 1 \rangle}| \\ |T1 \cdot (Q^T)^{\langle 2 \rangle}| \\ |T1 \cdot (Q^T)^{\langle 3 \rangle}| \end{bmatrix} \rightarrow \begin{pmatrix} .57778 \\ .65332 \\ .56890 \\ .65334 \end{pmatrix}$$

the most acceptable variant is:

$$\max(R) = 0.65334 \quad . \quad R_3 = 0.65334$$

Complete formation of variants is the next:

$$R_3 > R_1 > R_0 > R_2 = 1 \quad (\text{affirmatively})$$

b) Weight coefficients of criterion are of different significance:

The vector of weight coefficients is given as:

$$T2 := (0.4 \ 0.2 \ 0.2 \ 0.1 \ 0.1)$$

The results, in other words,  
the elements of the vector R are:

$$R := \begin{bmatrix} |T2 \cdot (Q^T)^{\langle 0 \rangle}| \\ |T2 \cdot (Q^T)^{\langle 1 \rangle}| \\ |T2 \cdot (Q^T)^{\langle 2 \rangle}| \\ |T2 \cdot (Q^T)^{\langle 3 \rangle}| \end{bmatrix} \rightarrow \begin{pmatrix} .58889 \\ .58665 \\ .55779 \\ .68667 \end{pmatrix}$$

Applying maximization criterion the greatest value of the vector R suits to the fourth element.

$$\max(R) = 0.68667 \quad R_3 = 0.68667$$

The full arrangement of variants is the next one:

$$R_3 > R_0 > R_1 > R_2 = 1 \quad (\text{affirmatively}).$$

## 7. HEURISTIC RESEARCH

### 7.1 Optimal pipeline diameter [HR1.mcd]

**Example** Fix optimal pipe diameter for a pipeline through which water is pressed back from a source to a reservoir. Criterion function includes total annual charges. While searching through analyze four calculation cases. Ignore charges for water pumping. Solve the tasks for given discrete values of the diameter  $D_n$  [18]. Measurement units suit to SI system.

*Starting parameters*

Number of variants in analysis and calculation:  $n := 1..4$

Water elevation at the source  $Z1_n$  and in the reservoir  $Z2_n$ :

 $Z1_n :=$  $Z2_n :=$ 

|     |
|-----|
| 125 |
| 125 |
| 125 |
| 125 |

|     |
|-----|
| 200 |
| 200 |
| 200 |
| 200 |

Flow of water in pumping station:  $Q := 0.4$

Asbestos–cement pipeline is long:  $L := 3000$

Investment charges  $I_n$  and pipe diameters  $D_n$  are:

 $I_n :=$  $D_n :=$ 

|      |
|------|
| 6500 |
| 7000 |
| 7500 |
| 7850 |

|     |
|-----|
| 0.6 |
| 0.7 |
| 0.8 |
| 0.9 |

Coefficients for transformation of investment charges into annual ones:  $\alpha := 0.15$

1. The coefficient of useful action of pumping station:  $\eta := 65\%$
2. Frictional resistance:  $\lambda := 0.02$
3. Number of hours in one year:  $G := 8333$
4. Gravitational constant:  $g := 9.81$
5. Parameter of horse – power costs:  $a := 16668$

**Solution**

Pipeline costs:  $Tcev_n := I_n \cdot L \cdot \alpha$

 $Tcev_n =$ 

|         |
|---------|
| 2925000 |
| 3150000 |
| 3375000 |
| 3532500 |

According to Derki-Vijbaha, formula, linear parameter is (length):

$$\Delta\Pi_n := \frac{8 \cdot \lambda \cdot L \cdot Q^2}{g \cdot \pi^2 \cdot (D_n)^5}$$

$$\Delta\Pi_n =$$

|        |
|--------|
| 10.201 |
| 4.72   |
| 2.421  |
| 1.343  |

Horse – power of pumping station: 
$$N_n := \frac{g \cdot Q}{\eta} \cdot (Z2_n - Z1_n + \Delta\Pi_n)$$

$$N_n =$$

|         |
|---------|
| 514.351 |
| 481.261 |
| 467.383 |
| 460.879 |

The difference between water at the resource and in the reservoir:

$$\Delta Z_n := Z2_n - Z1_n$$

$$\Delta Z_n =$$

|    |
|----|
| 75 |
| 75 |
| 75 |
| 75 |

Costs of independent part from diameter: 
$$T_{\Delta Z_n} := \frac{g \cdot Q \cdot a}{\eta} \cdot \Delta Z_n$$

$$T_{\Delta Z_n} =$$

|            |
|------------|
| 7546757.54 |
| 7546757.54 |
| 7546757.54 |
| 7546757.54 |

Costs of dependent part from diameter: 
$$T_{\Delta\Pi_n} := \frac{g \cdot Q \cdot a}{\eta} \cdot \Delta\Pi_n$$

$$T_{\Delta\Pi_n} =$$

|            |
|------------|
| 1026444.21 |
| 474899.16  |
| 243580.02  |
| 135169.61  |

Total costs: 
$$T_n := T_{cev_n} + T_{\Delta Z_n} + T_{\Delta\Pi_n}$$

$$T_n =$$

|            |
|------------|
| 11498201.7 |
| 11171656.7 |
| 11165337.6 |
| 11214427.1 |

Checking the values of costs function, the minimal value is  $T_3 = 11165337,6$  and to it suits the optimal value of diameter of  $D_3 = 800$  mm. Thus, it is accepted that:

**Fig. 7.1** Dependence of total expenses of pipeline diameter

## 8. MARKOV MODELS

### 8.1 The model for forecast consumers' orientation [MM1.mcd]

**Example** Orientation of clients for the products A, B and C at the  $t_0$  moment is presented by the vector of starting point [2].

$$V_0 := (0.55 \ 0.25 \ 0.2) \quad \text{or} \quad V_0 = (55 \ 25 \ 20) \%$$

Markov's matrix of transitional probabilities is given in the form:

$$M := \begin{pmatrix} 0.3 & 0.5 & 0.2 \\ 0.4 & 0.1 & 0.5 \\ 0.2 & 0.6 & 0.2 \end{pmatrix}$$

With the assumption of Markov matrix stationariness, determine:

- How many buyers decide for the products A, B and C after three year's period? Present graphically results in moments  $t = 0$  year and  $t = 3$  years.
- Define balanceable (final) state of demand of these products.

#### Solution and verification

For previous vector  $V_0$  and matrix  $M$  follows:

$$\sum V_0 = 1 \quad \sum (M^T)^{(0)} = 1 \quad \sum (M^T)^{(1)} = 1 \quad \sum (M^T)^{(2)} = 1$$

Vectors of state:

For the first year  $t=1$ :  $V1 := V0 \cdot M$   $V1 = (0.305 \ 0.42 \ 0.275)$   $\sum V1 = 1$

For the second year  $t=2$ :  $V2 := V1 \cdot M^2$   $V2 = (0.303 \ 0.389 \ 0.308)$   $\sum V2 = 1$

For the third year  $t=3$ :  $V3 := V2 \cdot M^3$   $V3 = (0.307 \ 0.379 \ 0.314)$   $\sum V3 = 1$

Enumerating (of) state vectors:  $V := \text{stack}(V0, V1, V2, V3)$   $V^{(0)} = \begin{pmatrix} 0.55 \\ 0.305 \\ 0.303 \\ 0.307 \end{pmatrix}$

Matrix of series now makes (progressions):  $V = \begin{pmatrix} 0.55 & 0.25 & 0.2 \\ 0.305 & 0.42 & 0.275 \\ 0.303 & 0.389 & 0.308 \\ 0.307 & 0.379 & 0.314 \end{pmatrix}$

Preparation for graphical interpretation:  $t := 0..3$   $A_t :=$   $B_t :=$   $C_t :=$

|               |               |               |
|---------------|---------------|---------------|
| $(V^{(0)})_0$ | $(V^{(1)})_0$ | $(V^{(2)})_0$ |
| $(V^{(0)})_1$ | $(V^{(1)})_1$ | $(V^{(2)})_1$ |
| $(V^{(0)})_2$ | $(V^{(1)})_2$ | $(V^{(2)})_2$ |
| $(V^{(0)})_3$ | $(V^{(1)})_3$ | $(V^{(2)})_3$ |

**Fig. 8.1** Graph (plot) of Markov's probabilities for different time moments

**Conclusion** It can be concluded that the product A that was in the greatest demand in the beginning of the period after the expiry of three periods falls on the third place and it points out that in that product one should not invest further. It is also concluded that one ought to invest into the product B, because it becomes leading product at the market.

### $\pi$ Stable balanceable state

Stable balanceable state is being defined on the basis of the system of matrix equations for balanceable state:

$$S \cdot M = S \quad \sum S = 1$$

### $\pi$ The solution of equations system

Initial values:  $S := \begin{pmatrix} \frac{5}{10} & \frac{4}{10} & \frac{3}{10} \end{pmatrix}$

Given  $S \cdot M - S = 0 \quad \sum S = 1$

$$(s1 \ s2 \ s3) := \text{MinErr}(S)$$

Solving this system of equations one gets vector of stable balanceable state W:

$$W := (s1 \ s2 \ s3) \quad W = (0.30657 \ 0.37956 \ 0.31387)$$

With verification:  $\sum W = 100\%$

Limit (bordering) matrix has come as enumerating of vectors:  $G := \text{stack}(W, W, W)$

$$G = \begin{pmatrix} 0.30657 & 0.37956 & 0.31387 \\ 0.30657 & 0.37956 & 0.31387 \\ 0.30657 & 0.37956 & 0.31387 \end{pmatrix}$$

## 8.2 Negotiability of assets (Credits, demands) [MM2.mcd]

**Example** In order to apply the procedure of analysis and foreseeing of negotiability of assets, we shall suppose in this example that Markov's matrix elements present modifications of the state of demands during one month period, as well that this is a stationary matrix. We estimate that: probability that demands with due date to one month will be cased is 0,5; probability that withholding of these demands will be written off (non-negotiable) makes 0; probability of withholding of these claims in state of demanding up to 30 days makes 0,2; while probability that these demands will pass into state of negotiability in the term of 30-90 days makes 0,3. Similarly, for demands (claims) that are in the fourth state, in other words with due date of 30-90 days, are supposed the next values of transitional probabilities [1]:

$$P_{0,3} := 0.45$$

$$P_{1,3} := 0.1$$

$$P_{2,3} := 0.15$$

$$P_{3,3} := 0.3$$

In view of these information's, Markov's matrix of transitional probabilities can be presented in the form of:

$$P := \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0.5 & 0 & 0.2 & 0.3 \\ P_{0,3} & P_{1,3} & P_{2,3} & P_{3,3} \end{pmatrix}$$

In order to determine fundamental matrix we shall divide the matrix P in the way described in the chapter about vectors and matrices.

$$I := \text{submatrix}(P, 0, 1, 0, 1) \quad I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \quad O := \text{submatrix}(P, 0, 1, 2, 3) \quad O = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$$

$$A := \text{submatrix}(P, 2, 3, 0, 1) \quad A = \begin{pmatrix} 0.5 & 0 \\ 0.45 & 0.1 \end{pmatrix}$$

$$B := \text{submatrix}(P, 2, 3, 2, 3) \quad B = \begin{pmatrix} 0.2 & 0.3 \\ 0.15 & 0.3 \end{pmatrix}$$

Fundamental matrix will be:  $F := (I - B)^{-1}$   $F = \begin{pmatrix} 1.359 & 0.583 \\ 0.291 & 1.553 \end{pmatrix}$

Markov's matrix of transitional probabilities is now:  $K := F \cdot A$   $K = \begin{pmatrix} 0.942 & 0.058 \\ 0.845 & 0.155 \end{pmatrix}$

The elements of the first sort of the matrix X indicate probability of demands negotiability with due date up to 30 days. So, it can be seen that probability that these claims will be cashed makes 94,2 %. Probability that these claims will be written off is 5,8%. The second sort elements that show final values of demands negotiability with due date up to 30-90 days, have similar interpretation. It is expected that 84,5% of these demands will be cashed, while 15,5% will remain uncollected. If we suppose that company at certain moment has 10000 dinars of claims with due date up to 30 days and 40000 dinars with due date up to 30-90 days, then the vector of demands is:

$$Q := (10000 \quad 40000)$$

Amount of demands that will be cashed (written off) at the end of one month, we get on the basis:

$$Q_c := Q \cdot K \quad Q_c = (43203.9 \quad 6796.1)$$

As it can be seen, from the total amount of 50000 dinars, that are company claims from this example, we may expect that 43204 will be cashed, while 6796 dinars of demands will be written off. The same result we can get in view of the vector equation:

$$Q_c := Q \cdot \left[ \left( \text{submatrix}(P, 0, 1, 0, 1) - \text{submatrix}(P, 2, 3, 2, 3) \right)^{-1} \right] \cdot \text{submatrix}(P, 2, 3, 0, 1)$$

$$Q_c = ( 43203.9 \quad 6796.1 )$$

## 9. MASS QUEUEING

### 9.1 The system of queueing M/G/1/ infinite [MQ1.mcd]

**Example** In a stockroom for heavy machines a high crane is efficient 75% of time. Studying the time for hoist and carrying has given the mean time of 10,5 minutes and standard aberration 8,8 minutes [26].

- How frequent is average series of calling for service (hoist, carrying and lowering by crane) and what time on the average is necessary for service.
- If average service time would be 8 minutes with standard aberration of 6 minutes, how are in that case reduced wanted characteristics?

#### Solution

It is theoretically M/G/1 endless process. The calculation parameters are (the) next:

$$\rho_1 := 0.75 \quad \tau_1 := 10.5 \cdot \text{min} \quad \tau_2 := 8 \cdot \text{min} \quad \sigma_1 := 8.8 \cdot \text{min} \quad \sigma_2 := 6 \cdot \text{min}$$

$$\text{Service frequency:} \quad \mu_1 := \frac{1}{\tau_1} \quad \mu_1 = 5.71 \text{ hr}^{-1}$$

$$\text{Flow intensity:} \quad \lambda := \rho_1 \cdot \mu_1 \quad \lambda = 4.29 \text{ hr}^{-1}$$

$$\text{Mean time of crane delay (retention):} \quad t_1 := \frac{\rho_1 \cdot (1 + \mu_1^2 \cdot \sigma_1^2)}{2 \cdot \mu_1 \cdot (1 - \rho_1)} \quad t_1 = 26.81 \text{ min}$$

If delay time is 8 minutes, then is:

$$\mu_2 := \frac{1}{\tau_2} \quad \mu_2 = 7.5 \text{ hr}^{-1} \quad \rho_2 := \frac{\lambda}{\mu_2} \quad \rho_2 = 0.571$$

so crane utilization is reduced on 57,1% of time, and makes:

$$t_2 := \frac{\rho_2 \cdot (1 + \mu_2^2 \cdot \sigma_2^2)}{2 \cdot \mu_2 \cdot (1 - \rho_2)} \quad t_2 = 8.33 \text{ mir}$$

then is:  $\Delta t := t_1 - t_2 \quad \Delta t = 18.48 \text{ mir}$

and that means that waiting time is reduced for 18,5 minutes (70%).

## 9.2 Sixchannel model of mass queueing [MQ2.mcd]

**Example** Sixchannel system of mass queueing of buyers functions on the assumption that average speed of queueing on/ per channel  $m = 45$  clients per hour, and that average speed of coming  $\lambda = 225$  clients per hour (on all  $k = 6$  channels). Queueing charges on one channel make  $C_1 = 21$  /mu/hour/. Determine basic parameters of system working regime and check validity of opening the seventh service channel in case that the cost made by clients waiting in front of the channel,  $C_2 = 12$  /mu/hour/. Here are known the next data:

$$\mu := 45 \cdot \text{hr}^{-1} \quad \lambda := 225 \cdot \text{hr}^{-1} \quad c_1 := 21 \quad c_2 := 12 \cdot \text{hr}^{-1} \quad k := 6$$

### Solution

Queueing factor on (per) channel  $\rho := \frac{\lambda}{\mu} \quad \rho = 5$

Queueing factor of the system  $\rho_s := \frac{\rho}{k} \quad \rho_s = 0.833$

Probability of the state when in the queueing system there are no clients, and in the stationary work system, is equal:

$$P_0 := \left( \sum_{x=0}^k \frac{\rho^x}{x!} + \frac{\rho^k}{k!} \cdot \frac{\rho_s}{1 - \rho_s} \right)^{-1} \quad P_0 = 0.00451$$

For all values  $x < k$ , state probabilities in stationary work system are determined through the relation:

$$x := 0..k \quad P_x := \frac{\rho^x}{x!} \cdot P_0$$

in single form:  $P_0 = 0.00451 \quad P_3 = 0.09400 \quad P_6 = 0.09792$

$$P_1 = 0.02256 \quad P_4 = 0.11750$$

$$P_2 = 0.05640 \quad P_5 = 0.11750$$

or in vector form:

$$\begin{pmatrix} P_0 \\ P_1 \\ P_2 \\ P_3 \\ P_4 \\ P_5 \\ P_6 \end{pmatrix} = \begin{pmatrix} 0.00451 \\ 0.02256 \\ 0.05640 \\ 0.09400 \\ 0.11750 \\ 0.11750 \\ 0.09792 \end{pmatrix}$$

Average number of clients that waits for service:  $G := \frac{\rho^6}{k!} \cdot \frac{\rho s}{(1 - \rho s)^2} \cdot P_0 \quad G = 2.94$

Average total of clients that waits is queued in service channels:

$$Q := 1 \cdot P_1 + 2 \cdot P_2 + 3 \cdot P_3 + 4 \cdot P_4 + 5 \cdot P_5 + 6 \cdot (1 - P_0 - P_1 - P_2 - P_3 - P_4 - P_5) \quad Q = 5$$

Average number of clients delaying in the queueing system:  $R := G + Q \quad R = 7.938$

Average time of clients waiting in queue  $\tau := \frac{G}{\lambda} \quad \tau = 47.001 \text{ s} \quad \tau = 0.013 \text{ hr}$

Average time of clients delayin in the system (waiting and queueing)

$$T := \tau + \frac{1}{\mu} \quad T = 0.0353 \text{ hr} \quad T = 2.12 \text{ mir}$$

Specific costs of delaying on account of clients waiting for service

$$T_v := c_2 \cdot G \cdot \tau \quad T_v = 0.46$$

Then follows the statement that it is not economically to open the seventh working place for the job of queueing clients.

## 10. SIMULATION MODELING

### 10.1 Random number generation [SM16.mcd]

In order to perform efficiently numerical modeling of random phenomena that can be described by functions, it is necessary to possess random number generator. As basis often is used random number uniformly disposed in standard interval [0,1]. In that case one may use Mathcad function

$runif(N,0,1)$ . With the help of incorporated function  $rnd(\theta)$  is generated random number, uniformly arranged in interval  $[0,\theta]$ , where limit value  $\theta$  is real number, greater than zero. Such method of generation is a more general case than it is offered by generation function  $runif$ . Application of this function is especially found in process modeling in technique (technology), where there are vectors of disturbing action on the system of random character. Meanwhile, by its nature the numbers of the type  $rnd(\theta)$  are pseudorandom, but as statistical tests indicate, they are verified as adequate replacement for real random numbers.

**Example** Random numbers sometimes ought to be disposed in an interval different than  $[0,1]$ , or there are necessary only integer numbers. By generation of twelve uniformly arranged random numbers in the interval  $[a,b]$  are achieved by the next model.

$$a := -3 \quad b := 3 \quad n := 0..11 \quad S_n := a + (b - a) \cdot rnd(1)$$

$$S^T = (-2.99 \quad -1.84 \quad 0.51 \quad -0.9 \quad 1.94 \quad -1.96 \quad 1.26 \quad -1.18 \quad -2.45 \quad -2.12 \quad 2.93 \quad -2.29)$$

if integer numbers are wanted, then is applied the function:  $S_n := round[a + (b - a) \cdot rnd(1)]$

$$S^T = (-3 \quad -1 \quad 2 \quad 2 \quad 1 \quad 1 \quad 3 \quad -1 \quad 2 \quad 0 \quad 2 \quad -3)$$

#### $\pi$ The model with deterministic function $f(x)$

**Example** The function  $rnd(\theta)$  is often used in an operand of a complex function. How much is the trend of that complex function. How much is the trend of that complex function “disturbed” by the influence of the function  $rnd(\theta)$ , directly depends on the value  $\theta$ , what may be noted in the next examples.

Incremental scaling of the axis of abscissae:  $x := 1, 1.15..16$

Chosen deterministic function:  $f(x) := \exp\left(\sin\left(2 \cdot \frac{x}{\pi}\right)\right)$

$f(x) =$

|       |
|-------|
| 1.812 |
| 1.951 |
| 2.088 |
| 2.22  |
| 2.343 |
| 2.453 |
| 2.548 |
| 2.625 |
| 2.679 |
| 2.711 |
| 2.718 |
| 2.7   |

**Fig. 10.1** Graph (plot) of the function with determinated trend

$\pi$     **Model of the function  $f(x)$  with weaker trend disturbance**

The function  $f(x)$  with added operand  $rnd(\theta)$ :  $f(x) := \exp\left(\sin\left(2 \cdot \frac{x}{\pi}\right)\right) + rnd(0.3)$

**Fig. 10.3** Graph (plot) of the function with random trend-variable with weaker trend

$\pi$     **Model of the function  $f(x)$  with marked trend disturbance**

The function  $f(x)$  with added operand  $rnd(\theta)$ :  $f(x) := \exp\left(\sin\left(2 \cdot \frac{x}{\pi}\right)\right) + rnd(1.4)$

**Fig. 10.4** Graph (plot) of the function with random trend-variable with more marked disturbed trend

**Advice** In order to make the procedures for random numbers more authentic, it is necessary to change periodically the value of “seed” of random numbers generator. This change is done by the option seed value for random numbers in the menu Math  $\bigcirc$  Options... Value “seed” is initial value of the numerical algorithm *rnd* and is defined that it is always equal or greater than one.

## 10.2 Simulating time reliability of technical system elements [SM2\_a.mcd]

**Example** The elements of the technical system S1, S2 and S3 are connected series-parallel according to the fig.1. On the basis of  $N=4000$  simulations, calculate mean time of system work without failure and compare it with theoretical result, if for every element, times of work without failure are exponentially disposed with known intensities of failure  $\lambda_1, \lambda_2$  and  $\lambda_3$ . Calculate relative aberration of theoretical and simulated mean value of time failure. Graphically present the functions of single and superponerated reliability.

**Fig. 10.5** The chart of the system S of technical elements in parallel connection

### $\pi$ Symbolical value solution of system reliability at series-parallel connection of elements

Functions of exponential reliability for three elements apart:

$$R_1(\lambda_1, t) := e^{-\lambda_1 \cdot t} \qquad R_2(\lambda_2, t) := e^{-\lambda_2 \cdot t} \qquad R_3(\lambda_3, t) := e^{-\lambda_3 \cdot t}$$

Total superponerated reliability function:

$$R(\lambda_1, \lambda_2, \lambda_3, t) := e^{-\lambda_1 \cdot t} \cdot [1 - (1 - e^{-\lambda_2 \cdot t}) \cdot (1 - e^{-\lambda_3 \cdot t})]$$

Symbolical solution for mean failure time of system at this combined connection of elements S1, S2 and S3:

$$\int_0^{\infty} R(\lambda_1, \lambda_2, \lambda_3, t) dt \left| \begin{array}{l} \text{assume, } \lambda_1 > 0 \\ \text{assume, } \lambda_2 > 0 \\ \text{assume, } \lambda_3 > 0 \end{array} \right. \rightarrow \frac{(\lambda_1^2 + 2 \cdot \lambda_1 \cdot \lambda_2 + 2 \cdot \lambda_1 \cdot \lambda_3 + \lambda_2^2 + \lambda_2 \cdot \lambda_3 + \lambda_3^2)}{(\lambda_1 + \lambda_3) \cdot (\lambda_1 + \lambda_2) \cdot (\lambda_1 + \lambda_2 + \lambda_3)}$$

$\pi$  **Theoretical value of system reliability at parallel connection of elements**

Failure intensities of single elements make:

$$S1: \lambda_1 := 0.35 \cdot 10^{-3} \quad S2: \lambda_2 := 0.28 \cdot 10^{-3} \quad S3: \lambda_3 := 0.32 \cdot 10^{-3}$$

Total theoretical reliability for parallel connection:

$$R(t) := R1(\lambda_1, t) \cdot [1 - (1 - R2(\lambda_2, t)) \cdot (1 - R3(\lambda_3, t))]$$

Theoretical mean time of system reliability at parallel connection of elements S1, S2 and S3:

$$T_{rp} := \int_0^{\infty} R(t) dt \quad \text{or concretely:} \quad T_{rp} \rightarrow 2027.2073217870547014$$

$$\text{Mean time of elements reliability 1:} \quad \int_0^{\infty} e^{-\lambda_1 \cdot t} dt \rightarrow 2857.1428571428571429$$

$$\text{Mean time of elements reliability 2:} \quad \int_0^{\infty} e^{-\lambda_2 \cdot t} dt \rightarrow 3571.4285714285714286$$

$$\text{Mean time of elements reliability 3:} \quad \int_0^{\infty} e^{-\lambda_3 \cdot t} dt \rightarrow 3125.0000000000000000$$

Mean time of elements reliability at series connection of elements S1, S2 and S3:

$\pi$  **Simulation of system reliability at parallel connection of elements**

Simulation of reliability time for S1:

Number of simulations:  $N := 4000$   $i := 0 \dots N - 1$

$$T1 := \text{rexp}(N, \lambda_1) \quad T1^T =$$

|   | 0     | 1      | 2     | 3    | 4 | 5    |
|---|-------|--------|-------|------|---|------|
| 0 | 173.5 | 3024.5 | 908.3 | 74.5 | 2 | 3350 |

Mean time of failure of elements for S1:  $\text{mean}(T1) = 2874.488$

Simulation of reliability time for S2:

$$T2 := \text{rexp}(N, \lambda 2)$$

$$T2^T =$$

|   | 0      | 1      | 2     | 3      | 4    | 5      |
|---|--------|--------|-------|--------|------|--------|
| 0 | 7364.8 | 2151.4 | 429.5 | 5456.6 | 7776 | 4018.9 |

Mean time of failure of elements for S2:

$$\text{mean}(T2) = 3569.163$$

Simulation of reliability time for S3:

$$T3 := \text{rexp}(N, \lambda 3)$$

$$T3^T =$$

|   | 0      | 1      | 2      | 3     | 4      | 5     |
|---|--------|--------|--------|-------|--------|-------|
| 0 | 2857.2 | 5425.8 | 1276.8 | 259.8 | 2962.9 | 259.7 |

Mean time of failure of elements for S3:

$$\text{mean}(T3) = 3113.725$$

Simulation of reliability time at parallel connection:

$$T_i := \text{if}(T1_i < \text{if}(T2_i > T3_i, T2_i, T3_i), T1_i, \text{if}(T2_i > T3_i, T2_i, T3_i))$$

$$T^T =$$

|   | 0      | 1       | 2      | 3     | 4    | 5       | 6       | 7       |
|---|--------|---------|--------|-------|------|---------|---------|---------|
| 0 | 173.54 | 3024.47 | 908.33 | 74.49 | 1.96 | 3349.97 | 2968.44 | 1761.88 |

Mean time of system failure at parallel connection:

$$\text{mean}(T) = 2040.245$$

Relative aberration of theoretical and simulation value is relatively little and it makes

$$\Delta := \frac{\text{mean}(T) - T_{rp}}{T_{rp}} \quad \text{tj.} \quad \Delta = 0.643\%$$

### $\pi$ Graphical interpretation of reliability function

**Fig. 10.6** Reliability functions for the system with series-parallel connected elements

As the number of replication increases, we note convergence of simulation result to very precise (one). This way of evaluation is enabled, because the results of referenced model are known, i.e. analytical one. In simpler cases of reliability modeling may be formed both models, then compare their results. In more complex cases, it is often is only possible to apply *Monte Carlo* method, so because of that reason it is called “method of the last output (solution)” [29].

## 11. MATRIX GAMES

### 11.1 Nonsingular matrix games [MG1.mcd]

**Example** Some two players may choose one of the next three numbers 0, 1 and 2. If addition of three numbers is even, then it goes to the second player, and if it is odd, to the first (one). Payment matrix for this game is:

$$A := \begin{pmatrix} 0 & 1 & -2 \\ 1 & -2 & 3 \\ -2 & 3 & -4 \end{pmatrix}$$

This matrix is singular, so here can not directly be applied the method of calculation for defining optimal mixed strategies. Meanwhile, if to every element of this matrix is added one, we shall get the matrix C.

$$B := \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix}$$

$$C := A + B \rightarrow \begin{pmatrix} 1 & 2 & -1 \\ 2 & -1 & 4 \\ -1 & 4 & -3 \end{pmatrix}$$

Inverse matrix of C matrix is equal:

$$C^{-1} \rightarrow \begin{pmatrix} \frac{13}{16} & \frac{-1}{8} & \frac{-7}{16} \\ \frac{-1}{8} & \frac{1}{4} & \frac{3}{8} \\ \frac{-7}{16} & \frac{3}{8} & \frac{5}{16} \end{pmatrix}$$

so the value of this modified game is:

$$V := \frac{1}{I^T \cdot C^{-1} \cdot I} \rightarrow 1$$

$$\text{where is: } I \equiv \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$$

because:  $I^T \cdot C^{-1} \cdot I = (1)$  in other words the value of starting game is equal to 0. optimal mixed strategies both for starting and modified game, are:

$$p := \frac{I^T \cdot C^{-1}}{I^T \cdot C^{-1} \cdot I} \rightarrow \begin{pmatrix} \frac{1}{4} & \frac{1}{2} & \frac{1}{4} \end{pmatrix} \quad \text{and} \quad q := \frac{C^{-1} \cdot I}{I^T \cdot C^{-1} \cdot I} \rightarrow \begin{pmatrix} \frac{1}{4} \\ \frac{1}{2} \\ \frac{1}{4} \end{pmatrix}$$

## 12. INVENTORY CONTROL

### 12.1 The calculation of optimal quantities of inventory with constant procurement [IC1.mcd]

**Example** A trade company plans to acquire  $Q = 1600$  /pieces/ (of) products during period  $\tau = 1$  /year/ (365 days). The buying price of the order is  $K_0 = 83$  /mu/, while annual charges for storage  $k_1 = 5,6$  /mu/kom/. Calculate:

- Optimal quantity  $q_0$  that ought to be contained in order so that total costs of inventories would be minimized.
- Calculate adequate quantity of products by order  $q_1$  and  $q_2$  /pieces/, if total charges of inventories increase for  $p = 50\%$ . Realize comparison in relation to optimal quantity of products.
- Give graphical presentation of flows for stockpiling and spending of product inventories for found numerical solutions.

#### Starting data

|  |              |
|--|--------------|
| Annual quantity of products /pieces/:  | $Q := 1600$  |
| Plan period /years/:   | $\tau := 1$  |
| Fixed costs of inventories ordering per series /mu/:                             | $k_0 := 83$  |
| Costs of inventories storage /mu/pieces/year/:                                   | $k_1 := 5.6$ |
| Percentage of increased costs for intervened storage in relation to regular one: | $p := 50\%$  |

#### Solution

|  |   |                |
|--|---|----------------|
| Optimal quantity of ordering /pieces/:       | $q_0 := \sqrt{\frac{2 \cdot Q \cdot k_0}{\tau \cdot k_1}}$          | $q_0 = 217.78$ |
| Optimal number of annual series /ser/years/: | $n := \frac{Q}{q_0}$  | $n = 7.35$     |
| Time period of one series /year/:            | $t := \frac{\tau}{n}$   | $t = 0.136$    |
| Minimal expenses of inventory /mu/:          | $F := k_0 \cdot \frac{Q}{q_0} + k_1 \cdot \frac{q_0}{2} \cdot \tau$ | $F = 1219.57$  |

$$\text{or: } \min F := \sqrt{2 \cdot k_0 \cdot k_1 \cdot Q \cdot \tau} \quad \min F = 1219.57$$

$$\text{Expenses increased for p.percentage /mu/:} \quad F_1 := (1 + p) \cdot F \quad F_1 = 1829.36$$

$$\text{Equation of total expenses:} \quad k_0 \cdot \frac{Q}{q} + k_1 \cdot \frac{q}{2} \cdot \tau - F_1 = 0$$

$$\text{that is equivalent to square equation:} \quad \tau \cdot \frac{k_1}{2} \cdot q^2 - F_1 \cdot q + k_0 \cdot Q = 0$$

$$\text{Solving root of equation on the basis of equation coefficients:} \quad q_{12} := \begin{pmatrix} k_0 \cdot Q \\ -F_1 \\ \frac{k_1 \cdot \tau}{2} \end{pmatrix}$$

$$\text{ORIGIN} := 1 \quad \begin{pmatrix} q_1 \\ q_2 \end{pmatrix} := \text{polyroots}(q_{12})$$

$$\text{Two solutions of square equation make /pieces/:} \quad \begin{pmatrix} q_1 \\ q_2 \end{pmatrix} = \begin{pmatrix} 83.185 \\ 570.158 \end{pmatrix}$$

$$\text{Alternative marks:} \quad q_1 := q_1 \quad q_2 := q_2$$

$$\text{Relation of two inventory quantities:} \quad u := \frac{q_2}{q_1} \quad u = 6.854$$

Graphical interpretation of increased inventory costs for p= 50%.

$$\text{Axis scaling of inventory quantity:} \quad q := 0, 1 \dots 650$$

$$\text{Function of total costs:} \quad f(q) := k_1 \cdot \frac{q}{2} \cdot \tau + k_0 \cdot \frac{Q}{q}$$

**Fig. 12.1** Functions of total and partial costs

Scaling of independent variable:  $x := 0, \frac{t}{200} \dots \text{ceil}(n) \cdot t$

Inventory programming in time for the first nine series:

$$f(x) := \begin{bmatrix} q_0 \cdot \left(1 - \frac{x}{t}\right) & \text{if } 0 \leq x \leq t \\ q_0 \cdot \left(2 - \frac{x}{t}\right) & \text{if } t < x \leq 2 \cdot t \\ q_0 \cdot \left(3 - \frac{x}{t}\right) & \text{if } 2 \cdot t < x \leq 3 \cdot t \\ q_0 \cdot \left(4 - \frac{x}{t}\right) & \text{if } 3 \cdot t < x \leq 4 \cdot t \\ q_0 \cdot \left(5 - \frac{x}{t}\right) & \text{if } 4 \cdot t < x \leq 5 \cdot t \\ q_0 \cdot \left(6 - \frac{x}{t}\right) & \text{if } 5 \cdot t < x \leq 6 \cdot t \\ q_0 \cdot \left(7 - \frac{x}{t}\right) & \text{if } 6 \cdot t < x \leq 7 \cdot t \\ q_0 \cdot \left(8 - \frac{x}{t}\right) & \text{if } 7 \cdot t < x \leq 8 \cdot t \end{bmatrix}$$

In view of previous data we can plan inventory quantities for operative period, during so-called “sowlike” diagram.

Sl. 12.2 Dijagram stanja zaliha u vremenu

## 12.2 Calculation of optimal inventory quantities with intervened order [IC2.mcd]

**Example** In the case that demand for inventory is greater than regularly acquired quantity, calculate.

- Optimal volume  $q$  of demand on inventories during time period  $t$  as well optimal volume of inventories  $p$  in the same time interval  $t$ . Because of that calculate intervened quantity  $\Delta q$ .
- Optimize interval cycle  $t$  (time between previous and next series), as well number of orders during time  $\tau = 12$  /months (365 days), if the next data are given:  
 $Q = 245000$  / pieces/ - total demand during year,  $k_1 = 80$  /mu/pieces/months / - unit costs of inventory maintenance,  $k_2 = 260/n_j$ /pieces/months/ - costs that appear an account of uneven delivering of inventory,  $k_0 = 7300$  /mu/- fixed costs of series acquisition.
- Determine necessary quantity  $p$  and  $\Delta q$ , if new quantity  $q = 3400$  /pieces/, and total costs of inventory in new conditions make  $F = 11900000$  /mu/. The other parameters remain the same as under b).
- Present graphically the case under c).

### Starting data

|  |               |
|--|---------------|
| Annual quantity of products /pieces/:                                    | $Q := 245000$ |
| Planned period of inventory converting /months/:                         | $\tau := 12$  |
| Fixed costs of inventory per series /mu/:                                | $k_0 := 7300$ |
| Costs of inventory storage /mu/pieces/months/:                           | $k_1 := 80$   |
| Costs of storage of intervened quantity of inventory /mu/pieces/months/: | $k_2 := 260$  |

### Solution

Optimal values of inventory /pieces/:  $q := \sqrt{\frac{2 \cdot Q \cdot k_0}{\tau \cdot k_1}} \cdot \sqrt{\frac{k_1 + k_2}{k_2}} \quad q = 2207.38$

$$p := \sqrt{\frac{2 \cdot Q \cdot k_0}{\tau \cdot k_1}} \cdot \sqrt{\frac{k_2}{k_1 + k_2}} \quad p = 1687.99$$

Optimal quantity of intervened acquisition /pieces/:  $\Delta q := q - p \quad \Delta q = 519.38$

Minimal total costs of inventory /mu/:

$$\min(F) := \sqrt{2 \cdot Q \cdot \tau \cdot k_0 \cdot k_1} \cdot \sqrt{\frac{k_2}{k_1 + k_2}} \quad \min(F) = 1620474.88$$

Checking of total costs for calculated optimal values of inventing /mu/:

$$\min F := k_0 \cdot \frac{Q}{q} + k_1 \cdot \frac{p^2}{2 \cdot q} \cdot \tau + k_2 \cdot \frac{(q - p)^2}{2 \cdot q} \cdot \tau \quad \text{so is:} \quad \min F = 1620474.88$$

Optimizing cycle of inventory converting /year/:  $t := \frac{\tau}{Q} \cdot q \quad t = 0.108$

Cycle of regular consumption /year/:  $t_1 := \frac{p}{q} \cdot t \quad t_1 = 0.083$

Consumption cycle of intervened quantity/year/:  $t_2 := t - t_1 \quad t_2 = 0.025$

Optimal number of series per year/series/year/:  $n := \frac{\tau}{t} \quad n = 110.99$

Necessary quantity in view of square equation solution per argument p. If: (nonoptimal) inventory quantity for series q and total costs F1:

$$q := 3400 \quad F1 := 1900000$$

Square equation of costs is:  $k_0 \cdot \frac{Q}{q_1} + k_1 \cdot \frac{p^2}{2 \cdot q_1} \cdot \tau + k_2 \cdot \frac{(q_1 - p)^2}{2 \cdot q_1} \cdot \tau - F1 = 0$

System variable:  $\text{ORIGIN} := 1$

with polynomial coefficients: 
$$p12 := \begin{bmatrix} k_0 \cdot \frac{Q}{q} + k_2 \cdot \frac{q}{2} \cdot \tau - F1 \\ -k_2 \cdot \tau \\ \tau \cdot \left( \frac{k_1 + k_2}{2 \cdot q} \right) \end{bmatrix}$$

Possible order  $p$  /pieces/ makes:  $\begin{pmatrix} p_1 \\ p_2 \end{pmatrix} := \text{polyroots}(p_{12})$

$$\begin{pmatrix} p_1 \\ p_2 \end{pmatrix} = \begin{pmatrix} 2141.8 \\ 3058.2 \end{pmatrix}$$

It follows that intervened quantity /pieces/in these conditions equal:

$$\Delta q_1 := q - p_1 \quad \Delta q_1 = 1258.204 \quad \Delta q_2 := q - p_2 \quad \Delta q_2 = 341.796$$

cycle of regular consumption /years/:  $t_{11} := \frac{p_1}{q} \cdot t \quad t_{11} = 0.068$

Consumption cycle of intervened quantity /year/:

$$t_{21} := t - t_{11} \quad t_{21} = 0.04 \quad t_{12} := \frac{p_2}{q} \cdot t \quad t_{12} = 0.097 \quad t_{22} := t - t_{12} \quad t_{22} = 0.011$$

Verification of costs solution /um/:

$$\begin{bmatrix} k_0 \cdot \frac{Q}{q} + k_1 \cdot \frac{p_1^2}{2 \cdot q} \cdot \tau + k_2 \cdot \frac{(q - p_1)^2}{2 \cdot q} \cdot \tau \\ k_0 \cdot \frac{Q}{q} + k_1 \cdot \frac{p_2^2}{2 \cdot q} \cdot \tau + k_2 \cdot \frac{(q - p_2)^2}{2 \cdot q} \cdot \tau \end{bmatrix} = \begin{pmatrix} 1900000 \\ 1900000 \end{pmatrix}$$

and it full suits to previously defined costs:

## 13. NETWORK PLANNING

### 13.1 Application of network technique PERT [PN1.mcd]

**Example** Determine expected values of time and standard deviation for set of six activities, given through network diagram (fig.13.1). Optimistic (a), the most probable (m) and pessimistic (b) times are presented in vector way. Check probability  $P$  of critical path realization in PERT network if the planned time of its realization  $T_p = 12$  days.

**Fig. 13.1** Network diagram PERT with marks of planning parameters

Known time parameters:  $T_p := 12$

$$a := \begin{pmatrix} 1 \\ 1 \\ 2 \\ 2 \\ 6 \\ 1 \end{pmatrix} \quad m := \begin{pmatrix} 2 \\ 3 \\ 3 \\ 4 \\ 8 \\ 2 \end{pmatrix} \quad b := \begin{pmatrix} 3 \\ 4 \\ 5 \\ 6 \\ 10 \\ 4 \end{pmatrix}$$

Expected times  $t$  and adequate standard deviations  $s$ :

$$t := \frac{1}{6} \cdot (a + 4 \cdot m + b) \quad s := \frac{b - a}{6}$$

$$t^T \rightarrow \left( 2 \quad \frac{17}{6} \quad \frac{19}{6} \quad 4 \quad 8 \quad \frac{13}{6} \right) \quad s^T \rightarrow \left( \frac{1}{3} \quad \frac{1}{2} \quad \frac{1}{2} \quad \frac{2}{3} \quad \frac{2}{3} \quad \frac{1}{2} \right)$$

Critical (the longest expected) flow  $T$  in network and deviations  $\sigma$  of time activities:

$$T := \max \left( \begin{pmatrix} t_0 + t_2 + t_5 \\ t_0 + t_3 \\ t_1 + t_4 \end{pmatrix} \right) \quad \sigma := \begin{bmatrix} \sqrt{(s_0)^2 + (s_2)^2 + (s_5)^2} \\ \sqrt{(s_0)^2 + (s_3)^2} \\ \sqrt{(s_1)^2 + (s_4)^2} \end{bmatrix} \quad \sigma = \begin{pmatrix} 0.782 \\ 0.745 \\ 0.833 \end{pmatrix}$$

$$T = 10.833 \quad \sigma_2 = 0.833$$

Probability  $P$  that critical flow will be realized in planned time  $T_p$  is relatively high and makes:

$$P := \text{pnorm}(T_p, T, \sigma_2) \quad P = 91.924\%$$

## 14. TESTING STATISTICAL HYPOTHESES

### 14.1 Test $\chi^2$ for verification the hypothesis about composition of empirical with theoretical exponential distribution [ST1.mcd]

**Example** It is supposed that obtained numerical data adapt to exponential Puason's distribution. Graphical presentation of Puason's distribution results for parameter experiments that have been given is the file SM8.prn. the obtained empirical results of quality characteristics are grouped in tables and graphically interpreted.

Function for import of empirical data:

$$P := \text{READPRN}(\text{"SM8.prn"})$$

Real values vector of quality characteristic:

$$P^T =$$

|   |   |   |   |   |   |    |   |   |   |   |    |    |    |    |    |    |    |    |    |
|---|---|---|---|---|---|----|---|---|---|---|----|----|----|----|----|----|----|----|----|
|   | 0 | 1 | 2 | 3 | 4 | 5  | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 |
| 0 | 0 | 4 | 3 | 2 | 4 | 10 | 3 | 6 | 4 | 5 | 4  | 4  | 3  | 7  | 5  | 5  | 2  | 3  | 3  |

### $\pi$ Statistic fixing of sample

Number of items in sample:  $n := \text{length}(P)$   $n = 200$

Midvalue and extreme values are:  $\text{mean}(P) = 3.975$   $\begin{pmatrix} \min(P) \\ \max(P) \end{pmatrix} = \begin{pmatrix} 0 \\ 10 \end{pmatrix}$

Interval indexes in P sample:  $i := 0..199$

The number of nonstandard (spoiled) pieces in a sample:  $NS := \sum P$   $NS = 795$

**Fig. 14.1** Value(s) arrangement of experimental data in relation to sample interval

Number of group intervals:  $h := \text{ceil}(5 \cdot \log(n))$   $h = 12$

Difference of extreme values of vector elements:  $\rho := \max(P) - \min(P)$   $\rho = 10$

Integer length of group differences:  $\Delta := \text{ceil}\left(\frac{\max(P) - \min(P)}{h}\right)$   $\Delta = 1$

Sample deviation:  $S(P) := \text{stdev}(P)$   $S(P) = 2.103$

Sample deviation:  $S(P) := \text{stdev}(P)$   $S(P) = 2.103$

Marginal values of intervals of fixed set of data:  $j := 0..h$

Marginal values vector of group intervals:  $l_j := \min(P) + \Delta \cdot j$

$$l^T =$$

|   |   |   |   |   |   |   |   |   |   |   |    |    |    |
|---|---|---|---|---|---|---|---|---|---|---|----|----|----|
|   | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| 0 | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |

Function of histograms in vector form:  $f := \text{hist}(l, P)$

$$f^T =$$

|   |   |    |    |    |    |    |    |    |   |   |    |    |
|---|---|----|----|----|----|----|----|----|---|---|----|----|
|   | 0 | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8 | 9 | 10 | 11 |
| 0 | 3 | 19 | 31 | 40 | 34 | 26 | 21 | 14 | 5 | 6 | 1  | 0  |

Funkcija fitovane normalne raspodele:  $ft(x) := n \cdot \Delta \cdot \text{dpois}(x, \text{mean}(P))$

Frequency of fitted data in h (of) group intervals:  $k := 0..h - 1$

Frequencies: empirical, theoretical sum of frequencies:

|         |             |                |                           |
|---------|-------------|----------------|---------------------------|
| $f_k =$ | $ft(l_k) =$ | $\sum f = 200$ | $\sum_k ft(l_k) = 199.83$ |
| 3       | 3.756       |                |                           |
| 19      | 14.93       |                |                           |

## $\pi$ Graphical interpretation of sample date distribution

**Fig. 14.2** Histogram and polygon of empirical and polygon of theoretical distribution

Difference function of empirical and theoretical values of distribution:

$$\Delta_k := f_k - ft(l_k)$$

**Fig. 14.3** "Stem" form of aberration function

**Note** In the next procedure has been performed grouping of starting and final values of frequencies, so that the value of these additions, as new elements frequencies vectors would not be lesser (fewer) than 5. In this case (it) is reduced with 12 on 9 elements given in the next tables (following).

Distribution correction of empirical and theoretical frequencies in (m+1) interval(s):

| m := (h - 1) - 4   |                                 | m := 8   |                | g := 0..m      |                |                |                |                |  |  |   |   |                     |                     |                     |                     |                     |                     |   |     |                  |  |                                    |  |        |       |        |        |        |       |       |  |       |       |       |       |        |       |       |        |       |   |        |       |       |        |        |       |       |      |      |

| 0.65   |                                 |  |                |                |                |                |                |                |  |  |   |   |                     |                     |                     |                     |                     |                     |   |     |                  |  |                                    |  |        |       |        |        |        |       |       |  |       |       |       |       |        |       |       |        |       |   |        |       |       |        |        |       |       |      |      |
| 9.29   |                                 |  |                |                |                |                |                |                |  |  |   |   |                     |                     |                     |                     |                     |                     |   |     |                  |  |                                    |  |        |       |        |        |        |       |       |  |       |       |       |       |        |       |       |        |       |   |        |       |       |        |        |       |       |      |      |

Testing is performed on the basis of *hi*-square test:

Empirical value of *hi*-square makes:

$$\chi^2 := \sum_g \frac{(F_g - F_{t_g})^2}{F_{t_g}} \quad \chi^2 = 5.072$$

Risk and certainty of hypothesis acceptance of (about) accordance of empirical and theoretical distribution:

$$\alpha := 0.10 \quad 1 - \alpha = 90\%$$

Number of unknown parameters of basic population (value  $\lambda$ ):  $s := 1$

Number of addends in the expression for *hi*-square value:  $r := m + 1 \quad r = 9$

Number of freedom degree:  $\nu := r - s - 1$

Theoretical (limited) value *hi*-square:  $\chi^2_g := \text{qchisq}(1 - \alpha, \nu) \quad \chi^2_g = 12.017$

Axis scaling of *hi*-square frequency:  $q := 0, 0.1 \dots 25 \quad k := 0 \dots 1$

**Fig. 14.4** Graphical presentation of hypothesis testing on the basis of distribution *hi*-square

## $\pi$ Results of testing with Hi-square test

Hi-square testing results may be quantitatively expressed by confirming or rejecting the next hypotheses:

- Hypothesis H0: Empirical data are submitted to the theoretical law of exponential distribution.
- Hypothesis H1: Deviation empirical from theoretical distribution has no random character.

Control vector of hi-square value:  $(0 \quad \chi^2 \quad \chi^2_g) = (0 \quad 5.072 \quad 12.017)$

Allowed hi-square values:  $0 < \chi^2 < \chi^2_g = 1$

Area of accepting H0 hypothesis:  $\text{pchisq}(\chi^2, v) < 1 - \alpha = 1$

- If:
- a) result is 1 we accept H0 hypothesis
  - b) result is 0 we accept H1 hypothesis.

**Conclusion** On the basis of confirming H0 hypothesis, we can with high probability of 90% claim that general population, from which the sample is analyzed, corresponds with supposed Puason's distribution law. Thus, hypothesis about this distribution does not contradict to empirical data.

## 14.2 Testing hypothesis about samples homogeneity in view of their variances [ST2.mcd]

**Example** Perform statistical  $F$ -hypothesis testing about marks equality in the mathematics subject with two pupils population on the basis of variances marks. Basic function of variances analysis is to find out are there statistically significant deviations between selected characteristics of two groups of among many groups in population. In pedagogical sense it e.g. can be marks of pupils knowledge, time periods of education in certain areas and the like. Thereby, values, that in principle, may be quantified. If it is found that that difference between characteristics of some groups statistically significant, then it is the proof that they do not belong to the same population, and that pedagogical concluding on their basis is unreliable. If it is found that that difference statistically insignificant (little or that is does not exist), then it is proof that there are groups, e.g. pupils, that belong to the same population and that pedagogical concluding on their basis reliable. Calculations of variances and all other procedures that follow are basically simple, if user has certain foreknowledge, so that he could explain inter and final results. They are established through checked statistical procedures. Here, these procedures will be illustrated on the results of application Fisher's  $F$ -test, by which we can find (non) equalities of marks at one subject. In this case is chosen mathematics and the example is made on the basis of methodology elaborated in the reference [27]. Testing of differences significances among statistical values is performed comparing value pairs from two series of statistical data, through analysis of variances. Significance of differences between two groups of pupils of the same generation in Mathematics subject. Set of marks for every group has been formed in separate files: group1.prn and group2.prn. Through Mathcad they are taken over as numerical data, forming vectors of S1 and S2 marks, through an address with articulated path. Number of pupils is not the same for every group, and for every pupil is recorded only one mark. On account of more efficient and more suitable application, separately will be interpreted and illustrated tabling of data (vector of numbers, i.e. marks) and later graphically presented  $F$ -test results.

$\pi$  of the first group:  $S1 := \text{READPRN}(\text{"gr1.pm"})$

$\pi$  of the second group:  $S2 := \text{READPRN}(\text{"gr2.pm"})$

$$S1^T =$$

|   |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |
|---|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|
|   | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 |
| 0 | 5 | 4 | 2 | 3 | 4 | 5 | 4 | 4 | 3 | 4 | 3  | 5  | 3  | 4  | 2  | 5  | 4  | 3  | 5  | 5  | 4  |

$$S2^T =$$

|   |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |
|---|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|
|   | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 |
| 0 | 4 | 3 | 1 | 4 | 5 | 4 | 5 | 3 | 4 | 2 | 4  | 5  | 3  | 5  | 5  | 4  | 4  | 5  | 2  | 5  | 4  |

Number of tested pupils of the first group:  $n1 := \text{length}(S1)$   $n1 = 59$

Number of tested pupils of the second group:  $n2 := \text{length}(S2)$   $n2 = 45$

Accepted probability of mistake of hypothesis accepting about homogeneity of marks:

$$\alpha := 0.10 \qquad \alpha = 10\%$$

Accepted probability of hypothesis accepting about homogeneity of marks:

$$1 - \alpha = 0.9 \qquad 1 - \alpha = 90\%$$

Standard deviation and variance of samples:

prve grupe:  $\text{stdev}(S1) = 0.9579$   $\text{var}(S1) = 0.918$

druge grupe:  $\text{stdev}(S2) = 1.0376$   $\text{var}(S2) = 1.077$

Objective mark of samples variance:

of the first group:  $v1 := \frac{n1}{n1 - 1} \cdot \text{var}(S1)$   $v1 = 0.9334$

of the second group:  $v2 := \frac{n2}{n2 - 1} \cdot \text{var}(S2)$   $v2 = 1.101$

Minimal, average and i maximal mark of samples:

of the first group:  $\min(S1) = 2$   $\text{mean}(S1) = 3.78$   $\max(S1) = 5$

of the second group:  $\min(S2) = 1$   $\text{mean}(S2) = 3.889$   $\max(S2) = 5$

$\pi$  **F-hypothesis testing of pupils' marks equality**

Number of freedom degrees:  
of the first group:

$$v1 := n1 - 1$$

$$v1 = 58$$

of the second group:

$$v2 := n2 - 1$$

$$v2 = 44$$

Upper threshold of significance:

$$F1 := qF\left(\frac{\alpha}{2}, v1, v2\right)$$

$$F1 = 0.6308$$

Lower threshold of significance:

$$F2 := qF\left(1 - \frac{\alpha}{2}, v1, v2\right)$$

$$F2 = 1.6134$$

Variable of F distribution:

$$F := \text{if}\left(\frac{v1}{v2} > 1, \frac{v1}{v2}, \frac{v2}{v1}\right)$$

$$F = 1.1796$$

**Note** The variable  $F$  is necessary to nominate to be greater than 1. In that sense *if* function is used.

Scaled values of independent variable:

$$q := 0, 0.02 \dots 4$$

$$k := 0 \dots 1$$

**Fig. 14.5** Graphical presentation of hypothesis testing on the basis of F-distribution

Control vector of limit  $F$  values:

$$(F1 \ F \ F2) = (0.6308 \ 1.1796 \ 1.6134)$$

$\pi$  Hypothesis  $H0$ :  $\sigma_{01}^2 = \sigma_{02}^2$  that variances of basic sets are mutually equal.

$\pi$  Hypothesis H1:  $\sigma_{01}^2 \neq \sigma_{02}^2$  that among variances of basic sets (there) are significant differences.

Interval of confidence:  $\frac{\alpha}{2} < pF(F, v_1, v_2) < 1 - \frac{\alpha}{2} = 1$

Area of H0 hypothesis accepting:  $F_1 < F < F_2 = 1$

Test criterion: If: a) result is 1 H0 hypothesis is accepted

b) result is 0 H1 hypothesis is accepted.

**Conclusion** Hypothesis H0 is confirmed. In that case it can be stated that estimates of variances are not significantly different, so there are no bases for supposition that one group of pupils has achieved better results in mathematics than the other one. Here presented method of pedagogical research may be base for development of extended model of pedagogical experiment on the basis of new and more detailed data.

Morgenstern, 1

Multicriteria optimization, 57

Multicriteria programming, 2

**N**

Network planning, 79  
 Neumann, Von, 1  
 Neuron networks, 2  
 Non-equation system, 10  
 Nonlinear programming, 2, 44, 46  
 Number of columns, 28  
 Number of rows, 28

**O**

One-dimensional process, 53  
 Optimal plan, 37  
 Optimal resources distribution, 53  
 Optimal solutions, 18  
 Optimal transport plan, 21, 32  
 Optimization, 4, 9  
 ORIGIN, 8, 12, 17, 22, 24, 31, 32, 38, 41

**P**

$pchisq(a,b)$ , 84  
 PDM (Precedence Diagramming Method), 2  
 PERT, 1, 79  
 $pnorm(x)$ , 80  
 Polachek, 1  
 Polynomial coefficients, 78  
 $polyroot(x)$ , 75, 78  
 Production program, 12, 16  
 Profit function, 15, 20, 24  
 Profit maximum, 21  
 Puason's distribution, 80

**Q**

$qchisq(x)$ , 83  
 Queueing factor, 66

**R**

Random number generation,  
67  
READPRN(x.prn), 80, 85  
*rnd(x)*, 68, 69  
*round(x)*, 68

**S**

Sample deviation, 79  
Simulation modeling, 67  
Simulation of reliability time,  
71, 72  
Solution verification, 17, 28  
Solution verification, 8  
*stack(x,y)*, 16, 18, 30, 62  
Statistical hypotheses, 80  
*stdev(x)*, 81, 85  
*submatrix(x)*, 64, 65  
Sum of capacities, 29  
Supplementary variables, 17  
System variable, 6

**T**

Taylor, Frederick, 1  
Transportation problem, 15,  
19, 26  
Tucker, 1

**U**

Ulman, 1

**V**

Valker, 1  
*var(x)*, 85, 86  
Vogel, 1

**Z**

Zadeh, 2
